TITLE OF THE INVENTION

INFORMATION RECORDING MEDIUM, INFORMATION RECORDING  
METHOD AND APPARATUS, AND INFORMATION PLAYBACK METHOD  
AND APPARATUS

5

BACKGROUND OF THE INVENTION

The present invention relates to an information  
recording medium, the contents of which can be played  
back by a plurality of types of information playback  
apparatuses provided by different manufacturers or  
10 distributors. The present invention also relates to  
an information recording method and apparatus for  
recording information on such information recording  
medium. Furthermore, the present invention relates  
to an information playback method and apparatus for  
15 playing back information recorded on such information  
recording medium.

In recent years, optical discs as information  
recording media have been extensively studied and  
developed. Optical discs include a CD (Compact disc)  
20 that has prevailed, and a DVD (Digital Video disc) that  
has a large storage size. The DVD includes a DVD-Video  
that can record/play back video information. The  
formats of information recorded on information  
recording media such as a CD, DVD, and the like are  
25 specified by standards described in standard books.  
The manufacturers of information recording media record  
information formatted according to the standards on

105934827.082304  
FOC280/2284560

information recording media.

Information recording/playback apparatuses that record information on information recording media and play back information recorded on the information recording media are manufactured by a plurality of manufacturers. However, as described above, since information is recorded on the information recording medium according to the standards, similar playback results are obtained irrespective of the manufacturers of information recording/playback apparatuses. That is, information recording/playback apparatuses can neither differentiate functions nor provide their originality. As a result, the principle of competition of the manufacturers does not work in term of functions, and technical development in the DVD-Video market may be disturbed.

Since information is recorded on an information recording medium according to fixed standards, functions cannot be quickly expanded in correspondence with advances of technologies. That is, in order to add a new function to an information recording medium, the standards must be upgraded in correspondence with the new function to be added. However, since much time is required for upgrading the standards, it is hard to add new functions in quick response to the advances of technologies.

# BRIEF SUMMARY OF THE INVENTION

The present invention has been made to solve the aforementioned problems, and has as its object to provide the following information recording medium, information recording method and apparatus, and information playback method and apparatus:

(1) an information recording medium which allows to achieve differentiation and originality of functions in units of models of information playback apparatuses provided by different manufacturers or distributors;

(2) an information recording method which records information on an information recording medium to be able to achieve differentiation and originality of functions in units of models of information playback apparatuses provided by different manufacturers or distributors;

(3) an information recording apparatus which records information on an information recording medium to be able to achieve differentiation and originality of functions in units of models of information playback apparatuses provided by different manufacturers or distributors;

(4) an information playback method which plays back information from an information recording medium on which information is recorded to be able to achieve differentiation and originality of functions in units of models of information playback apparatuses provided

by different manufacturers or distributors;

(5) an information playback apparatus which plays back information from an information recording medium on which information is recorded to be able to achieve differentiation and originality of functions in units of models of information playback apparatuses provided by different manufacturers or distributors;

(6) an information recording medium which has a data structure with high expandability of functions;

(7) an information recording method which records a data structure with high expandability of functions on an information recording medium;

(8) an information recording apparatus which records a data structure with high expandability of functions on an information recording medium;

(9) an information playback method which plays back information from an information recording medium on which a data structure with high expandability of functions on an information recording medium is recorded; and

(10) an information playback apparatus which plays back information from an information recording medium on which a data structure with high expandability of functions on an information recording medium is recorded.

An information recording medium according to the present invention comprises a first area which records

common information which can be commonly played back  
by a plurality of types of information playback  
apparatuses provided by different manufacturers or  
distributors and complies with common standards, a  
5 second area which records specific information which  
can be played back by only an information playback  
apparatus of a specific type provided by a specific  
manufacturer or distributor, and a third area which  
records link information indicating a link between the  
10 common information and specific information.

An information recording method according to the  
present invention comprises the steps of: recording  
common information which can be commonly played back  
by a plurality of types of information playback  
15 apparatuses provided by different manufacturers or  
distributors and complies with common standards;  
recording specific information which can be played  
back by only an information playback apparatus of  
a specific type provided by a specific manufacturer or  
20 distributor; and recording link information indicating  
a link between the common information and specific  
information.

An information recording apparatus according  
to the present invention comprises recording means  
25 for recording common information which can be  
commonly played back by a plurality of types of  
information playback apparatuses provided by different

0994827.082304  
T03280/284E60

manufacturers or distributors and complies with common standards, recording specific information which can be played back by only an information playback apparatus of a specific type provided by a specific manufacturer or distributor, and recording link information indicating a link between the common information and specific information.

An information playback method according to the present invention comprises the step of: comparing ID information stored in an information playback apparatus side of a specific type provided by a specific manufacturer or distributor, and ID information played back from an information recording medium, and playing back specific information, which is recorded on the information recording medium and can be played back by only the information playback apparatus of the specific type, on the condition that the two pieces of ID information match each other.

An information playback apparatus according to the present invention comprises ID information storage means for storing ID information, and playback means for comparing the ID information stored in the storage means and ID information played back from an information recording medium, and playing back specific information, which is recorded on the information recording medium and can be played back by only an information playback apparatus of a specific type,

on the condition that the two pieces of ID information match each other.

Additional objects and advantages of the invention will be set forth in the description which follows, and in part will be obvious from the description, or may be learned by practice of the invention. The objects and advantages of the invention may be realized and obtained by means of the instrumentalities and combinations particularly pointed out hereinafter.

10 BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

The accompanying drawings, which are incorporated in and constitute a part of the specification, illustrate presently preferred embodiments of the invention, and together with the general description given above and the detailed description of the preferred embodiments given below, serve to explain the principles of the invention.

FIGS. 1A to 1F are schematic views showing the data structure on an information recording medium capable of recording/playback;

FIG. 2 is a schematic view showing the directory structure of data files stored in a data area;

FIGS. 3A to 3J are schematic views showing the data structure in an AV file recorded on the information recording medium;

FIG. 4 is a view showing the recording locations of video objects along the sequence on the information

093483 0830  
T06280 4284660

recording medium;

FIG. 5 is a schematic view showing the data structure in an allocation map table;

FIG. 6 is a schematic view showing the data structure in PGC control information;

FIGS. 7A and 7B are views showing a playback example of video information using a PGC;

FIG. 8 is a schematic view showing the data structure in VTSI;

FIGS. 9A to 9F are views for explaining the VOB sequence order according to VOB I;

FIG. 10 is a schematic block diagram showing the arrangement of an information recording/playback apparatus;

FIG. 11 is a schematic block diagram showing the arrangement (physical system) of the information recording/playback apparatus;

FIG. 12 is a view showing common information, specific information, and link information recorded on the information recording medium, and the relationship between the common information and specific information;

FIGS. 13A to 13C are views showing the contents of one link information;

FIGS. 14A to 14C are views showing the contents that pertain to drive manufacturer ID information;

FIG. 15 is a view for explaining link pattern A;

FIG. 16 is a view for explaining link patterns B and C;

FIG. 17 is a view for explaining link pattern D;

FIGS. 18A and 18B are views for explaining  
5 category IDs in company A;

FIGS. 19A to 19C are views showing the internal data structure of edit control information;

FIGS. 20A to 20F are views showing the link and time relationships between management/control information complying with standards and link information;  
10

FIGS. 21A to 21D are explanatory views of a method of setting a designated location in "common information complying with standards" corresponding to each link information;

FIGS. 22A to 22C are explanatory views of the allocation of link information;  
15

FIG. 23 is a view for explaining the recording location (part 1) of specific information;

FIG. 24 is a view for explaining the recording location (part 2) of specific information;  
20

FIG. 25 is a view for explaining the recording location (part 3) of specific information;

FIGS. 26A and 26B are flow charts each showing the processing sequence for playing back and each displaying using link information by an information recording/playback apparatus available from company A;  
25

FIG. 27 is a flow chart showing the processing

sequence for simultaneously recording common information, link information, and specific information by the information recording/playback apparatus;

FIG. 28 is a flow chart showing the processing sequence for appending link information and specific information to common information already recorded on the information recording medium;

FIG. 29 is a flow chart showing the processing sequence executed when common information already recorded on the information recording medium undergoes an edit process;

FIG. 30 is a flow chart showing the processes for recording common information, link information, and specific information on the information recording medium;

FIG. 31 is a flow chart showing the processes for playing back information from the information recording medium on which common information, link information, and specific information have been recorded;

FIG. 32 is a view showing the correspondence between the data structure built on the information recording medium, and the data shown in FIGS. 1A to 1F;

FIG. 33 is a view showing data contained in an RTR Video Manager (RTR VMG);

FIG. 34 is a view showing data contained in a Manufacturer's Information Table (MNFIT); and

FIG. 35 is a view showing the data structure of

Manufacturer's Information #1 (MNFI#1).

DETAILED DESCRIPTION OF THE INVENTION

Preferred embodiments of the present invention will be described hereinafter with reference to the accompanying drawings.

[1] Outline of Data Structure on Information Storage Medium

The recording information contents (data structure) of information recorded on an information storage medium (Optical Disc or DVD\_RTR disc 1001) that can record and play back video information and music information shown in FIG. 1A will be explained below.

The data structure of information recorded on the information storage medium (optical disc 1001) is roughly divided, in the order from inner side 1006 in FIG. 1B, into:

- lead-in area 1002 having an embossed data zone whose light reflection surface has an embossed pattern, a mirror zone whose surface is flat (mirror surface), and a rewritable data zone capable of information rewriting;

- volume & file manager information 1003 that records information which is recorded on a rewritable data zone which can be recorded/rewritten by the user, and pertains to the entire file or volume of audio & video data;

- data area 1004 made up of a rewritable data zone

data and audio & video data, as shown in FIG. 1C.  
The recording order, each recording information size,  
and the like of computer data and audio & video data  
can be arbitrarily determined. Locations where the  
5 computer data are recorded will be referred to as  
computer data areas 1008 and 1010, and a location where  
the audio & video data are recorded will be referred to  
as audio & video data area 1009 hereinafter.

As shown in FIG. 1D, the data structure of  
10 information recorded in audio & video data area 1009  
contains:

- anchor pointer for control information 1015:  
information indicating the start location (start  
address) where control information 1011 is recorded  
15 in audio & video data area 1009;

- control information 1011: control information  
(corresponding to RTR.IFO shown in FIG. 2) required  
upon executing respective processes, i.e., video  
recording (audio recording), playback, editing, and  
20 search;

- video objects 1012: video recording information  
of video data contents;

- picture objects 1013: still picture information  
such as still pictures, slide pictures, and the like;

- 25 • audio objects 1014: audio recording information  
of audio data contents;

- thumbnail objects 1016: information such as

thumbnails used upon searching for a location the user wants to watch or upon editing; and so on.

Video objects 1012, picture objects 1013, audio objects 1014, and thumbnail objects 1016 shown in FIG. 1D mean groups of information classified in units of contents (data contents). Hence, all pieces of video information recorded on audio & video data area 1009 are contained in video objects 1012, all pieces of still picture information are contained in picture objects 1013, all pieces of audio information are contained in audio objects 1014, and all pieces of thumbnail information used in video information management and search are contained in thumbnail objects 1016.

VOB (video object) 1403 shown in FIG. 3D (to be described later) indicates a cluster of information recorded in AV file (i.e., audio & video file) 1401, and has a definition different from that of video objects 1012 shown in FIG. 1D. Note that similar terms often have quite different meanings.

Furthermore, as shown in FIG. 1E, the contents of control information 1011 include:

•AV data control information 1101: management information which manages the data structure in video object 1012 or manages information that pertains to the recording locations on optical disc 1001 as an information storage medium;

•playback control information 1021: control  
information required upon playback;

recording control information 1022: control  
information required upon recording (video/audio  
5 recording);

•edit control information 1023: control  
information required upon editing;

•thumbnail control information 1024: management  
information that pertains to thumbnails (thumbnail  
10 object) used to search for a location the user wants to  
watch in video data or to edit; and the like.

Note that Control information 1101 and playback  
control information 1021 shown in FIG. 1E correspond to  
RTR.IFO shown in FIG. 2.

15 As shown in FIG. 1F, the data structure in AV data  
control information 1101 shown in FIG. 1E is comprised  
of:

•allocation map table 1105: information which  
pertains to address setups along the actual layout,  
20 identification of recorded/unrecorded areas, and the  
like on the information storage medium (optical disc  
1001);

•video title set information 1106: time informa-  
tion (corresponding to RTR\_VMGI in FIG. 8) which  
25 indicates the overall information contents in AV file  
1401 shown in FIG. 3A, and includes link information  
among VOBs, grouping information of a plurality of VOBs

for management and search, a time map table, and the like;

·video object information 1107: information (corresponding to M\_AVFIT/S\_AVFIT in FIG. 8) which indicates information pertaining to each VOB in AV file 1401, and pertains to attribute (characteristic) information in units of VOBUs, and each VOBV contained in the VOB;

·PGC control information 1103: information that pertains to a video information playback program (sequence); and

·cell playback information 1108: information that pertains to the data structure of a basic video information unit upon playback.

The aforementioned contents are a brief explanation of the data structure shown in FIGS. 1A to 1F. Some additional explanations of each information will be given below.

Volume & file manager information 1003 records:

·information that pertains to the entire volume;  
·the number of files of contained PC data, and the number of files associated with AV data;  
·information associated with recording layer information and the like.

Especially, as the recording layer information, information 1003 records:

·the number of layers that form a disc (e.g.,

a single RAM/ROM two-layered disc has two layers,  
a single ROM two-layered disc also has two layers, and  
n single-sided discs are counted as n layers);

• a logical sector number range table (capacity in  
5 units of layers) assigned in units of layers;

• the characteristics (e.g., a DVD-RAM disc, a RAM  
section of a RAM/ROM two-layered disc, a CD-ROM, a CD-R,  
and the like) in units of layers;

an assigned logical sector number range table  
10 (including rewritable area capacity information of each  
area) in units of zones on a RAM area of each layer;  
and

• unique ID information of each layer (e.g., to  
find out a disc exchange event in a multi-disc pack).  
15 With this information, continuous logical sector  
numbers can be set even for a multi-disc pack or  
RAM/ROM two-layered disc to handle such discs or disc  
as a single, large volume space.

Playback control information 1021 records:

20 • information that pertains to a playback sequence  
which combines PGCs;

• information (a sequence for continuously playing  
back all recorded cells) indicating a pseudo recording  
location considering the information storage medium as  
25 a single tape like a VTR or DVC in relation to the  
above information;

• information that pertains to simultaneous

playback on a plurality of screens having different kinds of video information;

•search information: information which records cell IDs corresponding to search categories, and a table of start times in a given cell, and allows the user to select and directly access the video information of interest; and the like.

Recording control information 1022 records:

•program reservation recording information and the like.

Furthermore, edit control information 1023 records:

special edit information in units of PGCs (corresponding time setup information and special edit contents are described as EDL information); and

file conversion information (which converts a specific field in an AV file into a file such as an AVI file that can undergo special editing on a PC, and designates the storage location of the converted file).

Thumbnail control information 1024 describes:

•management information that pertains to thumbnail objects 1016 (designation information of the recording location of each thumbnail picture in audio & video data area 1009 and a VOB or cell associated with each thumbnail picture, location information in a VOB or cell associated with each thumbnail picture, and the like (the VOB and cell will be explained in detail

later upon explaining the contents of FIGS. 3A to 3J)).

The directory structure of data files in the data area will be described below.

5 All pieces of information are recorded in units of files in data area 1004 in FIG. 1B, and the relationship among data files is managed by the directory structure shown in FIG. 2.

10 Referring to FIG. 2, a plurality of subdirectories 1451 are contained within root directory 1450 to allow easy classification in units of recorded file contents. In the embodiment shown in FIG. 2, data files that pertain to computer data recorded on computer data areas 1008 and 1010 shown in FIG. 1C are recorded under subdirectory 1457 for computer data storage, and audio & video data recorded on audio & video data area 1009 are recorded under rewritable video title set RW\_VTS 1452. On the other hand, upon copying video information recorded on a DVD Video disc or (DVD Audio disc) to the disc shown in FIG. 1A, data are copied under 15 video title set VIDEO\_TS 1455, and audio title set AUDIO\_TS 1456.

20 Control information 1011 in FIG. 1D is recorded as a single file for recording/playback video management data. In the embodiment in FIG. 2, that information has file name RW\_VIDEO\_CONTROL.IFO (or real time recording information; abbreviated as RTR.IFO). 25 Furthermore, identical information is also recorded as

backup information with file name RW\_VIDEO\_CONTROL.BUP.

In the embodiment shown in FIG. 2, all of  
video objects (RTR\_MOV.VRO) 1012, picture objects  
(RTR\_STO.VRO) 1013, audio objects (RTR\_STA.VRO) 1014,  
5 and thumbnail objects 1016 are recorded as single AV  
file 1401 (the file name in the embodiment in FIG. 2  
is RW\_OBJECT.OB).

Rewritable additional information 1454 (not shown  
in FIGS. 1A to 1F) that can be used upon recording/  
10 playing back video information can be simultaneously  
recorded. That information is recorded as a single  
file, which has file name RW\_ADD.DAT in the embodiment  
in FIG. 2.

FIGS. 3A to 3J show an example of the data  
15 structure in an AF file. As shown in FIG. 3B, entire  
AV file 1401 forms single VTS (video title set) (or RTR  
movie object RTR\_MOV.VRO) 1402. VTS 1402 contains  
a group of a plurality of VOBs (video objects) 1403,  
1404, and 1405, which are separated into a plurality of  
20 part\_of\_titles (or a plurality of chapters) 1407 and  
1408 in accordance with the contents of audio & video  
data and the order of information recorded in AV  
file 1401.

VOBs 1403, 1404, and 1405 in FIG. 3D are defined  
25 as sets of audio & video data recorded in AV file 1401,  
and have definition contents different from video  
objects 1012 shown in FIG. 1D that primarily serve the

purposes of classification items of video information/  
still picture information/audio information/thumbnail  
information and the like. Hence, VOBs 1403, 1404, and  
1405 in FIG. 3D record not only information classified  
5 into video objects 1012, but also information  
classified into picture objects 1013, audio objects  
1014, and thumbnail objects 1016.

Associated VOBs are grouped into a plurality of  
PTTs (part\_of\_titles or chapters) 1407 and 1408 based  
10 on information contents recorded in VOBs 1403, 1404,  
and 1405. That is, PTTs 1407 and 1408 are formed as  
sets of one or a plurality of VOBs. In the embodiment  
shown in FIG. 3C, PTT 1408 is formed by two VOBs, i.e.,  
VOBs 1404 and 1405, and PTT 1407 is formed by one VOB  
15 1403 alone.

Minimum basic units of video information are  
called VOBUS (video object units) 1411 to 1414, and  
data in VOBs 1403 to 1405 are formed as sets of VOBUS  
1411 to 1414, as shown in FIG. 3E.

20 MPEG1 or MPEG2 is prevalently used as the video  
information compression technique in VOBs 1403 to 1405.  
MPEG segments video information into groups called GOPs  
in 0.5-sec increments, and compresses video information  
in units of GOPs. Video information compression units  
25 of VOBUS 1411 to 1414 are formed to have nearly the  
same size as that of GOP in synchronism with GOP.

Furthermore, VOBUS 1411 to 1414 are recorded while

being segmented into sectors 1431 to 1437 in units of 2,048 bytes. Sectors 1431 to 1437 record raw video information, sub-picture information, audio information, and dummy information in units of packs in the form of pack structures, i.e., V\_PCKs (video packs) 1421, 1425, 1426, and 1427, SP\_PCK (sub-picture pack) 1422, A\_PCK (audio pack) 1423, and DM\_PCK (dummy pack) 1424. Each dummy pack size is 2,048 bytes. However, since each pack has a 14-byte pack header at the start of it, the information size recorded in each pack is 2,034 bytes.

Note that DM\_PCK (dummy pack) 1424 is inserted for the purposes of:

addition of information to be additionally recorded after video recording (for example, memo information indicating that after-recording information is inserted into an audio pack and replaced by a dummy pack is inserted in sub-picture information (a sub-picture pack) and is replaced by a dummy pack).

The recording area of a DVD-RAM (DVD\_RTR) disc as an example of the information storage medium (optical disc 1001) shown in FIG. 1A is segmented into a plurality of sectors. 2,048-byte data can be recorded per sector. In this DVD-RAM disc, recording/playback is done in units of sectors (2,048 bytes). Hence, when a DVD-RAM disc is used as the information storage medium (optical disc 1001), the respective packs are recorded in units of sectors 1431 to 1437, as shown in

FIG. 3F.

As shown in FIGS. 3B and 3D, VTS (video title set or RTR\_MOV.VRO) 1402 is formed by a sequence of all VOBs 1403 to 1405 in AV file 1401. By contrast, a playback sequence described in playback control information (pack control information) 1021 can designate an arbitrary range in an arbitrary VOB, and can play it back in an arbitrary playback order.

Basic video information units upon playback are called cells 1441, 1442, and 1443. Each of cells 1441, 1442, and 1443 can designate an arbitrary range in an arbitrary VOB, but cannot make designation across a plurality of VOBs (one cell cannot set a range by linking a plurality of VOBs).

In the embodiment shown in FIG. 3G, cell 1441 designates one VOB 1412 in VOB 1403, cell 1442 designates whole VOB 1404, and cell 1443 designates the range of only a specific pack (V\_PCK 1427) in VOB 1414.

Information indicating a video information playback sequence is set by PGC (program chain) 1446, and is described by designating a single cell or by link information of a plurality of cells. For example, in the embodiment shown in FIG. 3H, PGC (program chain) 1446 forms a playback program as a link of cells 1441, 1442, and 1443 (the relationship between the cell and PGC will be described in detail later).

VOBU 1403 in FIG. 3D can contain not only video

information but also audio information. In this case,  
VOBU 1411 that forms VOB 1403 contains V\_PCK 1421 and  
SP\_PCK 1422 that construct a video part, and A\_PCK 1423  
and DM\_PCK (for after recording) 1424 that construct  
5 an audio part.

The video part is formed by a sequence header and  
GOP header composed of some contents on the start side  
of V\_PCK, MPEG I-picture composed of the contents of  
a V\_PCK group, a sequence end code composed of some  
10 contents on the end side of V\_PCK, and sub-picture unit  
SPU composed of the contents of SP\_PCK.

The audio part contains audio data to be played  
back in synchronism with still picture playback using  
I-picture of the video part, and is comprised of one or  
15 more audio frames.

The contents of allocation map table 105 in  
FIG. 1F will be described below with reference to  
FIG. 4.

As described above, the recording area of the  
20 DVD-RAM disc is segmented into a plurality of sectors,  
and logical sector numbers (LSNs) are continuously  
assigned in ascending order from the inner side.

A case will be examined below wherein video  
information is recorded in data area 1004 of the  
25 information storage medium (optical disc 1001) in the  
following sequence.

1. An area for recording AV file 1401 is assured

2. Data of VOB#1 1461 is recorded in a continuous  
5 area (b < c) from logical sector numbers (LSN) b+1 to c  
in the area for recording AV file 1401.

10           As a result of the above processes in 1. to 3.,  
three unrecorded areas "from a+1 to b", "from c+1 to d",  
and "from e+1 to g" in logical sector numbers (LSN)  
remain in AV file 1401. When video information of  
VOB#3 with a large data size is recorded in these  
15 unrecorded areas, the following processes are required.

5. First segmented data 1463 of VOB#3 is recorded  
20 in a continuous area ( $a < b$ ) from logical sector  
numbers (LSN)  $a+1$  to  $b$ .

25            7. Last segmented data 1465 of VOB#3 is recorded  
in a continuous area ( $f < g$ ) from logical sector  
numbers (LSN)  $f+1$  to  $g$ .

As a result, unrecorded area 1460 "from e+1 to f" in logical sector numbers (LSN) remains in AV file 1401. FIG. 4 shows the distribution of physical recorded positions of VOBs in AV file 1401 as a result of the above processes in 1. to 7.

As can be seen from the above description, when data in AV file 1401 is partially erased or when new data is additionally recorded in an unrecorded area in AV file 1401, single VOB data must be segmented and recorded at a plurality of locations like data 1463, 1464, and 1465 of VOB#3.

Allocation map table 1105 shown in FIG. 1F shows information indicating the distribution of physical positions of identical data distributed and recorded in AV file 1401 in units of VOBs. FIG. 5 shows the information contents of allocation map table 1105 taking the data allocation shown in FIG. 4 as an example. Allocation map table 1105 is comprised of distribution information 1621 of positions of unrecorded areas, and a plurality of pieces of distribution information 1622, 1623, and 1624 of positions of recorded data in units of VOBs.

A cluster of data units having continuous logical sector numbers in each VOB will be defined as an "extent". In the embodiment shown in FIG. 4, data of VOB#3 are recorded as three extents. In the above example, since an area from logical sector numbers a+1

to b has continuous logical sector numbers, this area forms "extent#γ 1473". That is, the recording positions of the data of VOB#3 are distributed to three locations, i.e., extent#γ 1473, extent#δ 1474, and extent#ε 1475.

5           The position distribution information that pertains to unrecorded areas or each VOB in allocation map table 1105 shown in FIG. 5 records the number 1601, 1602, 1603, or 1604 of extents at its first position. After that, first address 1606, 1607, 1608, 1609, 1610, 10   or 1611 and size 1614, 1615, 1616, 1617, 1618, or 1619 of each extent are recorded. The first address is expressed by a "differential number" (or relative sector number) from the first logical sector number of AV file 1401. When each first address is expressed 15   by a differential number, if the entire contents of AF file 1401 are transplanted to another information recording medium, information in allocation map table 1105 need not be changed, thus improving file portability. In FIG. 5, the extent size is expressed 20   by the number of sectors. The extent size may be expressed by the last address of each extent in place of the number of sectors in FIG. 5.

          In the DVD-RAM disc (DVD\_RTR disc) format, information indicating a physical address on the 25   information storage medium (optical disc 1001) is called a physical sector number (PSN), the entire address used by the file system is called a logical

sector number (LSN), and an address defined on the file system in data area 1004 in FIG. 1A is called a logical block number (LBN), thus distinguishing PSN, LSN, and LBN from each other. However, if this convention is always observed, the description becomes complicated. For this reason, FIG. 5 uses an expression based on logical sector numbers (LSN) for the sake of easy understanding.

The contents of playback control information 1021 will be described below with reference to FIGS. 6 to 7B. PGC (program chain) control information 1103 in playback control information 1021 has the data structure shown in FIG. 6, and the playback order is determined by PGC and cells. PGC is a unit that designates the playback order of cells and executes a given playback sequence. On the other hand, each cell indicates a playback period that designates playback data in each VOB by the start and end addresses, as shown in FIGS. 3D to 3F.

PGC control information 1103 is composed of PGC information management information 1052, one or more search pointers 1053 and 1054 of PGC information, and a plurality of pieces of PGC Information 1055, 1056, and 1057.

PGC information management information 1052 contains information (number of PGC information) indicating the number of PGCs. Each of search pointers

1053 and 1054 of PGC Information points to the first position of each PGC information, and allows an easy search. Each PGC information 1055, 1056, or 1057 consists of PGC general information 1061, one or more pieces of program information (PGI#m), one or more cell IDs (or CI\_SRP#m), and one or more pieces of cell information (CI#m). PGC general information (PGC\_GI) 1061 contains information (number of cell playback information) indicating the playback time of PGC and the number of cells. Or PGC\_GI 1061 may contain information indicating the number of programs (PGs) and the number of search pointers (CI\_SRP) of cell information.

As shown in FIG. 7A, playback data are designated as a playback period in units of cells from cell-A to cell-F, and PGC information is defined in each PGC.

1. PGC#1 exemplifies a case wherein it is composed of cells that designate a continuous playback period, and its playback order is cell-A → cell-B → cell-C.

2. PGC#2 exemplifies a case wherein it is composed of cells that designate an intermittent playback period, and its playback order is cell-D → cell-E → cell-F.

3. PGC#3 exemplifies a case wherein playback can be done intermittently irrespective of the direction of playback or repetitive playback, and its playback order

is cell-E → cell-A → cell-D → cell-B → cell-E.

Control information (RTR.IFO) 1011 shown in FIG. 1D or 2 contains navigation data RTR\_VMG (real time recording video manager) corresponding to control information 1101 and control information 1021, as shown in FIG. 1E. This RTR\_VMG contains video title set information VTSI (or information RTR\_VMGI of RTR\_VMG) 1106, as shown in FIG. 1F.

This information (RTR\_VMGI) 1106 contains information used upon playing back a sequence of VOBs 1403, 1404, 1405, ..., shown in FIG. 3D.

The data structure and contents of RTR\_VMG in FIG. 1E (or RTR.IFO in FIG. 2) will be explained below with reference to FIG. 8.

As shown in FIG. 8, navigation data RTR\_VMG (control information RTR.IFO) is comprised of RTR video manager information (RTR\_VMGI), a movie AV file information table (M\_AVFIT), a still picture AV file information table (S\_AVFIT), original PGC information (ORG\_PGCI), a user-defined PGC information table (UD\_PGCIT), a text data manager (TXTDT\_MG), and a table (MNFIT) of information that pertains to the manufacturer.

RTR\_VMGI contained in this RTR\_VMG corresponds to video title set (VTS) information 1106 shown in FIG. 1F.

This information (RTR\_VMGI) 1106 contains VTS general information 1751, VOB sequence information 1752,

PTT information 1753, and VTS time map table 1754, as shown in FIG. 8.

Put otherwise, this information (RTR\_VMGI) 1106 contains a play list search pointer table (PL\_SRPT) corresponding to VOB sequence information 1752, and a video manager information management table (VMGI\_MAT) corresponding to VTS general information 1751.

Table PL\_SRPT contains information 1756 indicating the number of VOBs in VTS (or the number of play list search pointers and the end address of PL\_SRPT), information 1757 indicating the ID of the first VOB in a VOB sequence (or first play list search pointer PL\_SRP#1), information 1758 indicating the ID of the second VOB in the VOB sequence (or second play list search pointer PL\_SRP#2), and the like.

Each play list search pointer (PL\_SRP) contains information (PL\_TY) indicating the type of a play list, PGC number information (PGCN) corresponding to this play list, information (PL\_CREATE\_TM) indicating the date of creation of this play list, information (PRM\_TXTI) of primary text associated with this play list, number information (IT\_TXTI\_SRPN) of a search pointer of item text used in this play list, and thumbnail pointer information (THM\_PTRI) indicating a thumbnail picture corresponding to the recording contents of this play list.

The table (PL\_SRPT) that contains these pieces

of information 1756, 1757, 1758, ... corresponds to  
VOB sequence information 1752 contained in VTSI  
(RTR\_VMGI) 1106.

5 The contents of VTSI (RTR\_VMGI) 1106 can be  
summarized as follows.

That is, as shown in FIG. 8, the data structure in  
video title set information (or RTR\_VMGI) 1106 records:

•video title set general information 1751 ... This  
information pertains to general contents of a video  
10 title set (or RTR data in AV file 1401 in FIG. 2);

•video object sequence information 1752 ... In the  
data structure shown in FIGS. 3A to 3J, serial numbers  
are set for all VOBs in video title set 1402 (= AV  
file 1401). This information describes serial number  
15 information of VOBs according to this sequence;

•part\_of\_titles information 1753 ... Object data  
recorded in AV file 1401 are grouped in units of  
associated data for the purpose of each data management  
and search, and video title names are set in units of  
20 groups. The group (part\_of\_title) is formed of a set  
of VOBs. This information describes VOB information  
contained in each part\_of\_title; and

•video title set time map table 1754 ... This  
information pertains to VOB position information at  
25 specific time intervals according to the video object  
sequence in relation to VOBs which are classified into  
video objects 1012 and audio objects 1014 in video title

set 1402.

The detailed data structure in video object sequence information 1752 is shown on the right side in FIG. 8. That is, the total number 1756 of VOBs (or PL\_SRPTI) contained in the video title set is recorded at the first position. After that, VOB\_IDs (or PL\_SRP#1, PL\_SRP#2, ..., PL\_SRP#n) 1757, 1758, ... corresponding to serial numbers are recorded in the sequence (video object sequence) order.

The sequence indicated by video object sequence information 1752 can be arbitrarily set by the user or information recording/playback apparatus side in, e.g., "the recording order to AV file 1401 (ascending order of recording time)", "the recording allocation order on the information storage medium (optical disc) shown in FIG. 4", "the VOB size order", and the like. By sequentially determining the order of all VOBs in VTS (video title set) 1402, a user interface similar to a VTR that records video data on a single table can be provided.

For example, the following processes can be done using video object sequence information 1752:

- to search for a scene the user wants to watch by fast-forwarding (FF) or rewinding (FR) a tape;
- to confirm the entire recording contents by fast-forwarding (FF) the tape; and
- to search for an unnecessary recorded scene by

fast-forwarding (FF) or rewinding (FR) the tape, and to overwrite new video information on that scene.

The information contents of video object sequence information 1752 shown on the right side in FIG. 8 will be explained below with reference to FIGS. 9A to 9F.

A case will be examined first wherein VOB#1 to VOB#3 are recorded to have the allocation order on the information storage medium (optical disc) shown in FIG. 4, and this recording is done in the order of 1. to 7. described in "description of allocation map table contents". FIG. 9C shows the sequence order which is set for these data in "the recording order to AV file 1401 (ascending order of recording time)". Compared to FIG. 4, the allocation order from extent# $\alpha$  1471 to extent# $\zeta$  1470 has changed. "First VOB\_ID 1757 in the video object sequence" shown in FIG. 8 designates "VOB#1 1461" in FIG. 9C, and "second VOB\_ID 1758 in the video object sequence" designates "VOB#2 1462" in FIG. 9C.

FIG. 9F shows another embodiment designated by video object sequence information 1752. VOB#A 1771 and VOB#B 1772 belong to (are classified to) video objects (movie VOB information M\_VOBI#) 1012, VOB#C 1773, VOB#F 1776, and VOB#G 1777 to audio objects 1014, and VOB#D 1774 and VOB#E 1775 to picture objects (still picture VOB group information S\_VOGI#) 1013. In this way, the sequence order can be designated independently of the

VOB types. In FIG. 9F, VOBs (VOB#H 1778 and VOB#I 1779) that belong to thumbnail objects 1016 are set at the end of the sequence.

FIG. 10 is a block diagram for explaining the arrangement in the RTR video recorder. In this specification, reference numerals are indicated within blocks to save space.

The apparatus main body of the video recorder shown in FIG. 10 is roughly comprised of disc changer (disc drive unit) 1500 for rotating one to be used of one or a plurality of information storage media (optical discs) 1001, and executing recording and playback of video information with respect to optical disc 1001, encoder unit 1550 that constructs the video recording side, decoder unit 1560 that constructs the playback side, and system controller (MPU) 1530 which incorporates a ROM and RAM (semiconductor memory), and controls the operations of the apparatus main body.

Encoder unit 1550 comprises ADC (analog-to-digital converter) 1552, video encoder (V encoder) 1553, audio encoder (A encoder 1554), sub-picture encoder (SP encoder) 1555, formatter 1556, and buffer memory 1557.

ADC 1552 receives an external analog video signal + external analog audio signal from AV input 1542, or analog TV signal + analog audio signal from TV tuner 1544. This ADC 1552 converts the input analog video signal into digital data at, e.g., a sampling

frequency = 13.5 MHz and the number of quantization  
bits = 8. (More specifically, luminance component Y,  
color difference component Cr (or Y-R), and color  
difference component Cb (or Y-B) are respectively  
5 quantized by 8 bits.)

Likewise, ADC 1552 converts the input analog  
audio signal into digital data at, e.g., a sampling  
frequency = 48 kHz and the number of quantization  
bits = 16.

10 When an analog video signal and digital audio  
signal are input to ADC 1552, the digital audio signal  
passes through ADC 1552. (A process for reducing  
jitter superposed on a digital signal, a process  
for changing the sampling rate and the number of  
15 quantization bits, or the like without changing the  
contents of a digital audio signal may be done.)

When a digital video signal and digital audio  
signal are input to ADC 1552, these signals pass  
through ADC 1552 (for these digital signals, a jitter  
20 reduction process, sampling rate change process, or the  
like that do not change their contents may be done).

When still picture information sensed by digital  
camera 1543 is input in addition to the input video  
signals, it is directly input to V encoder 1553 without  
25 the intervention of ADC 1552.

A digital video signal component output from  
ADC 1552 is sent to formatter 1556 via video encoder

REC'D 34660

(V encoder) 1553. A digital audio signal component output from ADC 1552 is sent to formatter 1556 via audio encoder (A encoder) 1554. Or a still picture signal directly input to V encoder 1553 is sent from V encoder 1553 to formatter 1556.

V encoder 1553 has a function of converting the input digital video signal into a digital signal compressed at variable bit rate on the basis of the MPEG2 or MPEG1 specifications.

In digital camera 1543, still picture information is recorded in the bitmap or JPEG format. By contrast, in the present invention, a still picture is recorded on optical disc 1001 in the I-picture format of MPEG2. For this purpose, in the present invention, V encoder 1553 has format conversion functions of "bitmap → MPEG2", "JPEG → MPEG2", and the like.

A encoder 1554 has a function of converting the input digital audio signal into a digital signal (or linear PCM digital signal) compressed at fixed bit rate on the basis of the MPEG or AC-3 specifications.

When a digital video signal (for example, a signal from a DVD video player with an independent output terminal of a sub-picture signal) is input from AV input 1542, or when a DVD video signal with such data structure is broadcasted and is received by TV tuner 1544, the sub-picture signal component (sub-picture pack) in the video signal is input to sub-picture

encoder (SP encoder) 1555. Sub-picture data input to SP encoder 1555 is arranged into a predetermined signal format, and is then sent to formatter 1556.

5           Formatter 1556 executes predetermined signal processing of the input video signal, audio signal, sub-picture signal, and the like using buffer memory 1557 as a work area, and outputs recording data that matches a predetermined format (file structure) to data processor 1536.

10           In case of digital broadcast, a video signal is transmitted in the TS (transport stream) format of MPEG2. In general, when a video signal is recorded on information storage medium (optical disc) 1001 in the MPEG2 format, the PS (program stream) format is used.  
15           Hence, upon receiving digital broadcast, the received signal is directly sent from TV tuner 1544 to formatter 1556, which executes "TS → PS conversion".

            Standard encode process contents for creating the recording data will be briefly explained below.  
20           More specifically, when encoder unit 1550 shown in FIG. 10 starts an encode process, parameters required for encoding video (main picture) data and audio data are set. Main picture data is pre-encoded using the set parameters, and optimal code amount distribution  
25           for the selected average transfer rate (recording rate) is calculated. Then, the main picture data is encoded based on the code amount distribution obtained by

pre-encoding. At this time, audio data is encoded simultaneously.

As a result of pre-encoding, if it is determined that the data compression amount is insufficient (a  
5 desired video program cannot fall within information storage medium (optical disc) 1001 to be used), and pre-encoding can be re-done (if the source to be recorded is a source that can be repetitively played back such as a video tape, video disc, or the like),  
10 main picture data is partially re-encoded, and the previously pre-encoded main picture data portion is replaced by the re-encoded main picture data portion. With a series of processes described above, the main picture and audio data are encoded, and the average  
15 bit rate value required for recording can be greatly reduced.

Likewise, parameters required for encoding sub-picture data are set, and encoded sub-picture data is generated.

20 The encoded main picture, audio, and sub-picture data are combined, and are converted into the data structure of desired video objects.

More specifically, a cell as a minimum unit of main picture data (video data) is set, the configura-  
25 tion of cells that form a program chain, attributes of the main picture, sub-picture, and audio data, and the like are set (some of such attribute data use

information obtained upon encoding the respective data), and management information that contains various kinds of information which pertain to cells is recorded in the management information recording area (control information 1011 in FIG. 1D or RTR.IFO in FIG. 2).

The encoded main picture, audio, and sub-picture data are segmented into packs each having a predetermined size (2,048 bytes). Dummy packs that can be used in, e.g., after recording, are inserted into these packs as needed. Note that time stamps such as PTS (presentation time stamp), DTS (decode time stamp), and the like are described in packs other than dummy packs, as needed. As for PTS of sub-picture data, a time arbitrarily delayed from PTS of main picture data or audio data in the identical playback time band can be described.

Data cells are arranged in units of VOBUs to allow playback in the time code order of data, thus forming a VOB consisting of a plurality of cells.

Upon digitally copying video information from the digital output of the RTR video recorder shown in FIG. 10, since the contents of the cells, program chains, management tables, time stamps, and the like are determined in advance, they need not be created again.

The arrangement for reading/writing (recording and/or playing back) information from/to optical disc

1001 comprises disc drive unit (disc changer) 1500, information recording/reproducing unit 101, memory 1534, data processor 1536, and system time counter (or system time clock; STC) 1538.

5           Memory 1534 is used to buffer a given amount of data to be written on optical disc 1001 (data output from encoder unit 1550) via information recording/reproducing unit 101, and to buffer a given amount of data played back from optical disc 1001 (data input  
10           to decoder unit 1560) via information recording/reproducing unit 101.

          For example, when memory 1534 comprises a 4-Mbyte semiconductor memory (DRAM), it can buffer recording or playback data for approximately 8 seconds at an average  
15           recording rate of 4 Mbps. When memory 1534 comprises a 16-Mbyte EEPROM (flash memory), it can buffer recording or playback data for approximately 30 seconds at an average recording rate of 4 Mbps. Furthermore, when  
20           memory 1534 comprises a 100-Mbyte, very small HDD (hard disc drive), it can buffer recording or playback data for 3 minutes or more at an average recording rate of 4 Mbps.

          Also, memory 1534 can also be used to temporarily store recording information when optical disc 1001 is  
25           used up during video recording, until optical disc 1001 is exchanged by a new disc.

          When information recording/reproducing unit 101

09934827.082304

uses a high-speed recording/reproducing unit having a speed equal to or higher than double speeds, memory 1534 can also be used to store readout data exceeding a normal amount read out from the drive per unit time.

5 When memory 1534 buffers readout data upon playback, even when an optical head (not shown) has caused read errors due to vibration shock or the like, playback data buffered by memory 1534 can be used instead, thus preventing a playback image from being discontinued.

10 If an external card slot (not shown in FIG. 10) is provided to the RTR video recorder, the EEPROM can be offered as an option IC card. On the other hand, if an external drive slot or SCSI interface is provided to the RTR video recorder, the HDD can be offered as  
15 an option extension drive.

When a personal computer is used as a DVD video recorder by software, the free area of a hard disc drive or main memory of the personal computer itself can be used as memory 1534 shown in FIG. 10.

20 Under the control of system controller (MPU) [incorporating the ROM and RAM] 1530, data processor 1536 shown in FIG. 10 performs:

•supply of a video information signal to be recorded from encoder unit 1550 to information  
25 recording/reproducing unit 101;

•transfer of a video information signal played back by information recording/reproducing unit 101 to

09934827.082304  
FOC22807.234866

another unit;

- rewrite of management information (control information 1011) recorded on information storage medium (optical disc) 1001;

5       ·partial deletion of video information and management information (control information 1011 or RTR.IFO or RTR\_VMG) as data recorded on information storage medium (optical disc) 1001; and the like.

10       System controller 1530 includes an MPU (or CPU), a ROM as an IC memory written with control programs and the like, and a RAM as an IC memory that provides a work area required for executing programs.

15       Of the execution results of system controller 1530, the contents the user of the RTR video recorder should know are displayed on display/input panel 1548 of the RTR video recorder.

20       Note that the control timings of disc changer 1500, information recording/reproducing unit 101, data processor 1536, and encoder unit 1550 and/or decoder unit 1560 by system controller (MPU) 1530 can be determined based on time data supplied from STC 1538 (video recording/playback are normally executed in synchronism with time clocks from STC 1538, but other processes may be executed at timings independently of

25       STC 1538).

Decoder unit 1560 comprises separator 1562 for separating the respective packs from video information

with the pack structure recorded on optical disc 1001,  
memory 1563 used upon executing pack separation and  
other signal processes, video decoder (V decoder) 1564  
for decoding main picture data (the contents of video  
5 packs) separated by separator 1562, sub-picture decoder  
(SP decoder) 1565 for decoding sub-picture data (the  
contents of sub-picture packs) separated by separator  
1562, audio decoder (A decoder) 1568 for decoding  
audio data (the contents of audio packs) separated by  
10 separator 1562, video processor 1566 for appropriately  
mixing sub-picture data from SP decoder 1565 with video  
data output from V decoder 1564, i.e., superposing  
sub-picture data such as menus, highlight buttons,  
superimposed dialogs, and the like on main picture data,  
15 and outputting them, video digital-to-analog converter  
(V·DAC) 1567 for converting the digital video output  
from video processor 1565 into an analog video signal,  
and audio digital-to-analog converter (A·DAC) 1569 for  
converting the digital audio output from A decoder 1568  
20 into an analog audio signal.

The analog video signal (analog video information  
signal) output from V·DAC 1567, and the analog audio  
signal output from A·DAC 1569 are supplied to an  
external component (not shown; a multi-channel stereo  
25 system having two to six channels + monitor TV or  
projector) via AV output 1546.

## Information Recording/reproducing Unit

As means for implementing the aforementioned basic functions, the information recording/reproducing unit executes:

5       •a process for tracing (tracking) a focused beam spot along a track (not shown) on information recording medium 201;

10       •a process for switching information recording/reproducing/erasing modes by changing the limit amount of a focused beam spot with which information recording medium 201 is irradiated; and

      •a process for converting externally input recording signal d into an optimal signal to attain high-density recording at the low error rate.

15       <B> Mechanical Structure and Operations of Detection Section

      <B-1> Basic Structure of Optical Head 202 and Signal Detection Circuit

      <B-1-1> Signal Detection by Optical Head 202

20       Optical head 202 is basically constructed by a semiconductor laser element serving as a light source, photodetector, and objective lens (none of them are shown).

25       A laser beam emitted by the semiconductor laser element is focused on information recording medium (optical disc) 201 by the objective lens. The laser beam reflected by a light reflecting film or light reflective recording film of information recording

09934837-08304  
T03280-2284650

medium (optical disc) 201 is photoelectrically converted by the photodetector.

5 A detection current obtained by the photodetector is current-voltage-converted into a detection signal by amplifier 213. This detection signal is processed by focus/track error detection circuit 217 or binarization circuit 212. In general, the photodetector is divided into a plurality of photodetection areas, and individually detects changes in amount of light on the respective photodetection areas. These detection signals undergo arithmetic operations of sums and differences in focus/track error detection circuit 217 to detect focus and track errors. A change in amount of light reflected by the light reflecting film or light reflective recording film of information recording medium (optical disc) 201 is detected to reproduce a signal on information recording medium 201.

<B-1-2> Focus Error Detection Method

20 As a method of optically detecting the focus error amount, one of the following methods is often used:

•Astigmatism method: An optical element (not shown) for producing astigmatism is placed in a detection circuit for detecting a laser beam reflected by the light reflecting film or light reflective recording film of information recording medium (optical disc) 201, and a change in shape of the laser beam with which the photodetector is irradiated is detected.

A photodetection region is diagonally divided into four areas. Focus/track error detection circuit 217 calculates the difference between diagonal sums of detection signals obtained from the respective  
5 detection areas, thus obtaining a focus error detection signal.

•Knife edge method: A knife edge for asymmetri- cally intercepting some beam components of a laser beam reflected by information recording medium 201 is placed.  
10 A photodetection region is divided into two areas, and the difference between detection signals obtained from these detection areas is calculated to obtain a focus error detection signal.

<B-1-3> Track Error Detection Method

15 Information recording medium (optical disc) 201 has a spiral or concentric track, on which information is recorded. Information is reproduced or recorded/ erased by tracing a focused beam spot along the track. In order to stably trace the focused beam spot along  
20 the track, a relative positional displacement between the track and focused beam spot must be detected. As the track error detection method, the following methods or the like are normally used:

•DPD (Differential Phase Detection) method:

25 A change in intensity distribution of a laser beam reflected by the light reflecting film or light reflective recording film of information recording

medium (optical disc) 201 on the photodetector is detected. A photodetection region is diagonally divided into four areas. Focus/track error detection circuit 217 calculates the difference between diagonal sums of detection signals obtained from the respective detection areas, thus obtaining a track error detection signal.

•Push-Pull method: A change in intensity distribution of a laser beam reflected by information recording medium (optical disc) 201 on the photodetector is detected. A photodetection region is divided into two areas, and the difference between detection signals obtained from these detection areas is calculated to obtain a track error detection signal.

•Twin-Spot Method: A diffraction element or the like is inserted in a light transmission system between the semiconductor laser element and information recording medium 201 to wavefront-split light into a plurality of light components, and changes in amount of reflected light of  $\pm 1$ st-order diffracted light components with which information recording medium 201 is irradiated are detected. Photodetection areas for respectively detecting the amount of reflected light of  $\pm 1$ st-order diffracted light and that of  $-1$ st-order diffracted light are placed independently of the photodetection region for detecting a reproducing signal, and the difference between detection signals

from these areas is calculated to obtain a track error signal.

<B-1-4> Objective Lens Actuator Structure

The objective lens (not shown) for focusing a laser beam emitted by the semiconductor laser element on information recording medium 201 is movable in two axial directions in accordance with an output current from objective lens actuator drive circuit 218. The objective lens moves in:

- a direction perpendicular to information recording medium 201 to correct focus errors; and
- the radial direction of information recording medium 201 to correct track errors.

As prevalent objective lens actuator structures, the following schemes are used:

• Shaft slide scheme: A blade integrally formed on the objective lens moves along a central shaft. Upon moving the blade along the central shaft, focus errors are corrected; upon rotating the blade about the central shaft, track errors are corrected.

• 4-wire scheme: A blade integrally formed on the objective lens is coupled to a stationary system via four wires, and moves in two axial directions using elastic deformations of wires.

In either method, permanent magnets and coils are used, and the blade moves by supplying a current to the coil coupled to the blade.

<B-2> Rotation Control System of Information  
Recording Medium 201

Information recording medium (optical disc) 201 is  
mounted on turntable 221 that rotates by the driving  
5 force of spindle motor 204.

The rotational speed of information recording  
medium 201 is detected based on a reproduced signal  
obtained from information recording medium 201. More  
specifically, the detection signal (analog signal)  
10 output from amplifier 213 is converted into a digital  
signal by binarization circuit 212, and PLL circuit 211  
generates a constant period signal (reference clock  
signal) based on that digital signal. Information  
recording medium rotational speed detection circuit 214  
15 detects the rotational speed of information recording  
medium 201 using this clock signal, and outputs the  
detected speed.

A correspondence table that stores the information  
recording medium rotational speeds in correspondence  
20 with radial positions where information is reproduced  
or recorded/erased on information recording medium 201  
is recorded in advance in semiconductor memory 219.  
Upon determining the reproducing or recording/erasing  
position, controller 220 sets a target rotational speed  
25 of information recording medium 201 by looking up  
information in semiconductor memory 219, and informs  
spindle motor drive circuit 215 of that value.

Spindle motor drive circuit 215 detects the difference between this target rotational speed and the output signal (current rotational speed) of information recording medium rotational speed detection circuit 214, and supplies a drive current corresponding to this detection result to spindle motor 204 to control its rotational speed to be constant. The output signal from information recording medium rotational speed detection circuit 214 is a pulse signal having frequency corresponding to the rotational speed of information recording medium 201, and spindle motor drive circuit 215 controls both the frequency and pulse phase of this signal.

<B-3> Optical Head Moving Mechanism

Optical head moving mechanism (feed motor) 203 for moving optical head 202 in the radial direction of information recording medium 201 is provided.

As a guide mechanism for moving optical head 202, a rod-like guide shaft is often used. Optical head 202 moves using friction produced between this guide shaft and a bushing attached to a portion of optical head 202. Also, a method using a bearing that reduces the frictional force using rotation may be used.

In the driving force transmission method for moving optical head 202, a rotation motor (not shown) with a pinion (rotation gear) is inserted in a stationary system, and a rack as a linear gear that

meshes with the pinion is placed on the side surfaces  
of optical head 202, thereby converting rotation of  
the rotation motor into rectilinear motion of optical  
head 202. As another driving force transmission method,  
5 a linear motor scheme which inserts a permanent magnet  
in the stationary system, and rectilinearly moves  
optical head 202 by supplying a current to a coil set  
on optical head 202 may be used.

In either of the rotation or rectilinear motor  
10 scheme, basically, a current is supplied to the feed  
motor to generate a driving force for moving optical  
head 202. This driving current is supplied from feed  
motor drive circuit 216.

<C> Functions of Control Circuits

15 <C-1> Focused Beam Spot Trace Control

In order to correct focus or track errors,  
a circuit for supplying the driving current to an  
objective lens actuator (not shown) in optical head 202  
in accordance with the output signal (detection signal)  
20 from focus/track error detection circuit 217 is  
objective lens actuator drive circuit 218. Circuit 218  
includes a phase compensation circuit for improving  
characteristics in correspondence with the frequency  
characteristics of the objective lens actuator so as to  
25 attain high-speed response of objective lens movement  
up to a higher frequency region.

Objective lens actuator drive circuit 218 executes

in accordance with a command from controller 220:

- an ON/OFF process of focus/track error correction (focus/track loop);

- a process for moving the objective lens in the direction (focus detection) perpendicular to information recording medium 201 at low speed (executed when focus/track loop = OFF); and

- a process of moving a focused beam spot to a neighboring track position by slightly moving it in the radial direction (a direction across the track) of information recording medium 201 using kick pulses.

<C-2> Laser Light Amount Control

<C-2-1> Switch Process between Reproduction and Recording/Erasure

Reproduction and recording/erasure are switched by changing the amount of light of a focused beam spot with which information recording medium 201 is irradiated.

The following relation generally holds for an information recording medium using the phase change scheme:

[light amount upon recording] > [light amount upon erasing] > [light amount upon reproducing]

and, the following relation generally holds for an information recording medium using a magneto-optical scheme:

[light amount upon recording]  $\approx$  [light amount upon

09934827.082301  
T0E280.2284E660

erasing] > [light amount upon reproducing]

In case of the magneto-optical scheme, recording and erasure processes are controlled by changing the polarity of an external magnetic field (not shown) applied to information recording medium 201 upon recording/erasing.

Upon reproducing information, information recording medium 201 is continuously irradiated with light of a given amount.

When new information is recorded, light pulses of a given amount are intermittently superposed on the light upon reproducing. When the semiconductor laser element emits light pulses in a large amount, light reflective recording film of information recording medium 201 locally changes optically or in shape, thus forming a recording mark. When information is overwritten on a region where information has already been recorded, the semiconductor laser element emits light pulses.

When already recorded information is erased, the information recording medium is continuously irradiated with light in a given amount larger than that upon reproducing. Upon continuously erasing information, the amount of light to be irradiated is reset to that upon recording at specific periods, e.g., in units of sectors, so as to intermittently reproduce information parallel to the erasure process. That is, the erasure

process is done by intermittently reproducing the track number and address of a track to be erased, and confirming if an error occurs in the erased track.

<C-2-2> Laser Emission Control

5           Optical head 202 incorporates a photodetector (not shown) for detecting the amount of light emitted by the semiconductor laser element. Semiconductor laser drive circuit 205 detects any difference between the output (the detection signal of the amount of light emitted by  
10           the semiconductor laser element) from that photodetector and an emission reference signal supplied from recording/reproducing/erasing control waveform generation circuit 206, and feeds back a driving current to the semiconductor laser on the basis of the  
15           difference.

<D> Operations Pertaining to Control System for Mechanism

<D-1> Start-up Control

          When information recording medium (optical disc)  
20           201 is set on turntable 221 and start-up control is started, processes are done according to the following procedure.

          (1) Controller 220 informs spindle motor drive circuit 215 of a target rotational speed, and spindle  
25           motor drive circuit 215 supplies a driving current to spindle motor 204, thus initiating rotation of spindle motor 204.

(2) At the same time, controller 220 issues a command (execution command) to feed motor drive circuit 216, which supplies a driving current to optical head drive mechanism (feed motor) 203 to move optical head 202 to the innermost peripheral position of information recording medium 201. It is confirmed if optical head 202 has reached an inner peripheral position beyond a region of information recording medium 201 where information has been recorded.

(3) When spindle motor 204 has reached the target rotational speed, that status (status report) is sent to controller 220.

(4) Semiconductor laser drive circuit 205 supplies a current to the semiconductor laser element in optical head 202 in correspondence with a reproducing light amount signal sent from controller 220 to recording/reproducing/erasing control waveform generation circuit 206, thus starting laser emission.

\*The optimal amount of light upon reproducing varies depending on the type of information recording medium (optical disc) 201. Upon starting up, the lowest amount of light is set.

(5) Objective lens actuator drive circuit 218 controls to retract the objective lens (not shown) in optical head 202 to a position farthest from information recording medium 201 and to make the objective lens slowly approach information recording medium 201

in accordance with a command from controller 220.

(6) At the same time, focus/track error detection circuit 217 monitors the focus error amount, and sends status to controller 220 when the objective lens has  
5 reached the vicinity of an in-focus position.

(7) Upon receiving the status, controller 220 sends a command to objective lens actuator drive circuit 218 to turn on the focus loop.

(8) Controller 220 sends a command to feed motor  
10 drive circuit 216 while the focus loop is kept ON, thus slowly moving optical head 202 toward the outer periphery of information recording medium 201.

(9) At the same time, controller 220 monitors a reproduced signal from optical head 202. When optical  
15 head 202 has reached the recording region on information recording medium 201, controller 220 stops movement of optical head 202, and sends a command to objective lens actuator drive circuit 218 to turn on the track loop.

(10) An "optimal amount of light upon  
20 reproducing" and "optimal amount of light upon recording/erasing" recorded on the inner peripheral portion of information recording medium (optical disc) 201 are reproduced, and that information is recorded on  
25 semiconductor memory 219 via controller 220.

(11) Furthermore, controller 220 sends a signal corresponding to the "optimal amount of light upon

reproducing" to recording/reproducing/erasing control waveform generation circuit 206, thus re-setting the amount of light emitted by the semiconductor laser element upon reproducing.

5           (12) The amount of light emitted by the semiconductor laser element upon recording/erasing is set in correspondence with the "optimal amount of light upon recording/erasing" recorded on information recording medium 201.

10           <D-2> Access Control

          <D-2-1> Reproduce Information at Access

Destination on Information Recording Medium 201

          Information that pertains to recording locations and contents of information on information recording medium 201 varies depending on the type of information recording medium 201, and is normally recorded in

          • a directory management region: a group of such information is recorded on the inner or outer peripheral region of information recording medium 201;

20           • a navigation pack: the navigation pack is contained in a VOBS (Video Object Set) complying with the data structure of a PS (Program Stream) of MPEG2, and records information that pertains to the recording location of next video data;

25           or the like in information recording medium 201.

          When specific information is to be reproduced or recorded/erased, information in the aforementioned

09934837-083304

region is reproduced, and an access destination is determined based on the information obtained therefrom.

<D-2-2> Coarse Access Control

Controller 220 calculates the radial position of the access destination to obtain the distance between the calculated position and the current position of optical head 202.

Speed curve information that allows optical head 202 to reach the target position in the shortest period of time with respect to the required moving distance is recorded in advance in semiconductor memory 219. Controller 220 reads out that information, and controls movement of optical head 202 by the following method according to the speed curve.

Controller 220 sends a command to objective lens actuator drive circuit 218 to turn off the track loop, and controls feed motor drive circuit 216 to start movement of optical head 202.

When the focused beam spot crosses a track on information recording medium 201, focus/track error detection circuit 217 generates a track error detection signal. Using this track error detection signal, the speed of the focused beam spot relative to information recording medium 201 can be detected.

Feed motor drive circuit 216 calculates the difference between the relative speed of the focused beam spot obtained from focus/track error detection

circuit 217, and the target speed information obtained as needed from controller 202, and feeds back the result to the driving current to be supplied to optical head drive mechanism (feed motor) 203, thus moving optical head 202.

As described in "<B-3> Optical Head Moving Mechanism", friction always acts between the guide shaft and bushing or bearing. When optical head 202 is moving at high speed, dynamic friction acts. However, at the beginning of movement and immediately before stop of movement, static friction acts since the moving speed of optical head 202 is low. At this time, since the relative frictional force increases (especially immediately before stop of movement), the gain of current to be supplied to optical head drive mechanism (feed motor) 203 is increased in accordance with a command from controller 220.

#### <D-2-3> Fine Access Control

When optical head 202 has reached the target position, controller 220 sends a command to objective lens actuator drive circuit 218 to turn on the track loop.

The focused beam spot is tracing along the track on information recording medium 201 to reproduce the address or track number of that portion.

The current focused beam spot position is detected from the reproduced address or track number.

Controller 220 calculates the number of error tracks from the target position to be reached, and informs objective lens actuator drive circuit 218 of the number of tracks required for moving the focused beam spot.

5           When objective lens actuator drive circuit 218 generates a pair of kick pulses, the objective lens slightly moves in the radial direction of information recording medium 201, thus moving the focused beam spot to a neighboring track position.

10           Objective lens actuator drive circuit 218 temporarily turns off the track loop, generates kick pulses corresponding in number to information from controller 220, and then turns on the track loop again.

15           Upon completion of fine access, controller 220 reproduces information (address or track number) at the position where the focused beam spot is tracing, and confirms that the beam spot is accessing a target track.

<D-3> Continuous Recording/reproducing/erasing Control

20           The track error detection signal output from focus/track error detection circuit 217 is input to feed motor drive circuit 216. In the aforementioned "start-up control" and "access control", controller 220 controls feed motor drive circuit 216 not to use  
25           the track error detection signal.

After it is confirmed by access that the focused beam spot has reached a target track, some track error

099427 082304  
102280 2284650

detection signals are supplied as driving current to optical head moving mechanism (feed motor) 203 via motor drive circuit 216 in response to a command from controller 220. This control continues during the  
5 period in which the reproducing or recording/erasing process continues.

The central position of information recording medium 201 is slightly decentered from that of turntable 221. When some track error detection signals  
10 are supplied as the driving current, entire optical head 202 moves finely in correspondence with decentering.

When the reproducing or recording/erasing process continues for a long period of time, the focused beam  
15 spot position gradually moves toward the inner or outer periphery. When some track error detection signals are supplied as the driving current to optical head moving mechanism (feed motor) 203, optical head 202 gradually  
20 moves toward the inner or outer periphery in correspondence with the driving current.

In this manner, the load on track error correction of the objective lens actuator is reduced, and the track loop can be rendered stable.

<D-4> End Control

25 When the operation is to end upon completion of a series of processes, the processes proceed in accordance with the following procedure.

(1) Controller 220 sends a command to objective lens actuator drive circuit 218 to turn off the track loop.

5 (2) Controller 220 sends a command to objective lens actuator drive circuit 218 to turn off the focus loop.

(3) Controller 220 sends a command to recording/reproducing/erasing control waveform generation circuit 206 to stop emission of the semiconductor laser element.

10 (4) Controller 220 informs spindle motor drive circuit 215 of zero reference rotational speed.

<E> Flow of Recording Signal/Reproduced Signal to Information Recording Medium

15 <E-1> Signal Format Recorded on Information Recording Medium 201

As shown in FIG. 11, the information recording/reproducing unit (physical system block) performs "appending of an error correction function" and "signal conversion of recording information (modulation/demodulation of a signal)" for a signal recorded on information recording medium 201 to meet requirements:

- to allow correction of recording information errors resulting from defects on information recording medium 201;
- 25 •to simplify a reproducing processing circuit to set DC components of a reproduced signal at zero; and
- to record information on information recording

[illegible][illegible][illegible][illegible][illegible][illegible][illegible]

[illegible]

[illegible]

Upon completion of appending inner and outer codes PI and PO, ECC encoding circuit 208 reads signals in units of 2,366 bytes corresponding to one sector from semiconductor memory 219, and transfers them to modulation circuit 207.

<E-2-2> Signal Modulation

In order to make the DC component (DSV: Digital Sum Value) of a reproduced signal approach zero, and to record information on information recording medium 201 at high density, modulation circuit 207 executes signal modulation as conversion of the signal format.

Modulation circuit 207 and demodulation circuit 210 include a conversion table that indicates the relationship between an original signal and modulated signal. Modulation circuit 207 segments a signal transferred from ECC encoding circuit 208 in units of a plurality of bits in accordance with a given modulation scheme, and converts segmented signals into other signals (codes) while looking up the conversion table.

For example, when 8/16 modulation (RLL(2,10) code) is used as the modulation scheme, there are two different conversion tables, which are switched as needed to make the DC component (DSV: Digital Sum Value) after modulation approach zero.

<E-2-3> Recording Waveform Generation

When a recording mark is recorded on information recording medium (optical disc) 201, the recording

scheme normally used includes two different schemes:

•mark length recording: "1" is located at the leading and trailing end positions of a recording mark; and

5       •mark position recording: the central position of a recording mark matches the "1" position.

10       Upon executing mark length recording, a long recording mark need be formed. In this case, when light with an amount required for recording is kept irradiated for a predetermined period of time, a "raindrop"-like recording mark, only a trailing end portion of which has a larger width, forms due to the heat accumulation effect of the light reflective recording film of information recording medium 201. In order to remove such shortcoming, when a long recording mark is formed, a plurality of divided recording pulses are used or the recording waveform is changed stepwise.

15       Recording/reproducing/erasing control waveform generation circuit 206 generates the aforementioned recording waveform in correspondence with a recording signal sent from modulation circuit 207, and sends it to semiconductor laser drive circuit 205.

<E-3> Flow of Signal Upon Reproducing

<E-3-1> Binarization & PLL Circuits

25       As described in "<B-1-1> Signal Detection by Optical Head 202", a signal on information recording medium 201 is reproduced by detecting a change in

amount of light reflected by the light reflecting film  
or light reflective recording film of information  
recording medium (optical disc) 201. A signal obtained  
by amplifier 213 has an analog waveform. Binarization  
5 circuit 212 converts that signal into a binary digital  
signal consisting of "1"s and "0"s using a comparator.

PLL circuit 211 extracts a reference signal upon  
reproducing information from the reproduced signal  
obtained by binarization circuit 212. PLL circuit 211  
10 incorporates a variable frequency oscillator. The  
frequencies and phases of a pulse signal (reference  
clock) output from that oscillator and the signal  
output from binarization circuit 212 are compared, and  
the comparison result is fed back to the oscillator  
15 output.

#### <E-3-2> Demodulation of Signal

Demodulation circuit 210 includes a conversion  
table that indicates the relationship between the  
modulated signal and demodulated signal. A signal is  
20 restored to an original signal by looking up the  
conversion table in response to the reference  
clock obtained by PLL circuit 211. The restored  
(demodulated) signal is recorded on semiconductor  
memory 219.

#### 25 <E-3-3> Error Correction Process

Error correction circuit 209 detects error  
positions from the signal saved on semiconductor memory

0934837.08301

219 using inner and outer codes PI and PO, and sets pointer flags of the error positions.

After that, signals at error positions are corrected as needed in correspondence with the error pointer flags while reading out signals from semiconductor memory 219, and are transferred to data I/O interface 222 after inner and outer codes PI and PO are removed.

A signal sent from ECC encoding circuit 208 is output as reproduced signal c from data I/O interface 222.

<<1>> Expansion Information Use Method for Common Information Complying with Standards

FIG. 12 shows the basic concept of the present invention.

For example, information recorded on an information recording medium (optical disc 1001) according to the standards set in a public place like DVD-Video is called common information 2001 complying with standards.

Common information 2001 complying with standards is separated into object information or contents information 2012 which indicates information of contents themselves of information such as video information, still picture information, audio information, and the like, and management/control information 2011 for managing/controlling that information. These two pieces of information comply

with the standards, and can be played back and edited by any drivers (information recording/playback apparatuses) irrespective of their manufacturers.

When an original function beyond those specified  
5 by the standards is provided by only a driver  
(information recording/reproducing apparatus) of  
a specific manufacturer, and information that pertains  
to the original function is recorded on the information  
recording medium (optical disc 1001), such information  
10 can be recorded on a recording region of specific  
information 2002 which can be used by only a specific  
manufacturer. Specific information 2002 which can  
be used by only a specific manufacturer is recorded  
on that region on the information recording medium  
15 (optical disc 1001), which is different from that of  
common information 2001 complying with standards.  
Information that pertains to contents themselves of  
information such as video information, still picture  
information, audio information, or the like of the  
20 information that can be played back by only the driver  
(information recording/playback apparatus) of the  
specific manufacturer is defined by specific object  
information (specific contents information) 2008  
that can be used by only a specific manufacturer.  
25 Information required for managing and controlling  
this specific object information (specific contents  
information) 2008 that can be used by only a specific

manufacturer is defined by management/control  
information 2006 that can be used by only a specific  
manufacturer.

Even the driver (information recording/playback  
5 apparatus) of the specific manufacturer having the  
original function basically operates according to  
function rules specified by the standards. Hence, the  
driver (information recording/playback apparatus)  
basically executes operations and processes using  
10 common information 2001 complying with standards, and  
executes special processes by reading out specific  
information 2002 which can be used by only a specific  
manufacturer in only a portion that requires a specific  
function. That is, a location or timing requiring  
15 specific information 2002 which can be used by only  
a specific manufacturer is set in association with the  
contents of common information 2001 complying with  
standards. Information that indicates association of  
specific information 2002 which can be used by only  
20 a specific manufacturer with common information  
2001 complying with standards is defined as "link  
information 2003".

The basic concept and objectives of the present  
invention are summarized as follows.

25       •A plurality of pieces of link information  
uniquely created by recorders (information recording/  
playback apparatuses) of a plurality of companies can

be parallelly stored and used.

•The need for ID assignment is obviated in a specific organization in association with manufacturer ID information that sets link information. As a result,  
5 no application for seeking permission/authorization of the specific organization is required, and a new manufacturer can freely enter the market.

•After video information is edited by a recorder (information recording/playback apparatus) of another  
10 company, the influence of edited video information on link information can be detected by a recorder (information recording/playback apparatus) of the self company.

FIGS. 13A to 13C show information contents  
15 recorded in one link information. The features of the information contents are summarized below.

(1) One link information can simultaneously indicate a plurality of link sources/link destinations:

•When an identical original function (a function  
20 that can be implemented by only a driver of a specific manufacturer) is to be designated at a plurality of locations in management/control information 2005 complying with standards, such parallel links set at a plurality of locations can reduce the number of pieces  
25 of link information required.

•When a plurality of original functions (functions that can be implemented by only a driver of a specific

manufacturer) are to be designated at a single location in management/control information 2005 complying with standards, such parallel links set at a plurality of locations can reduce the number of pieces of link information required.

(2) A method of allowing parallel storage and use of a plurality of pieces of link information uniquely created by recorders of a plurality of companies:

In the structure of the present invention, a plurality of pieces of link information can parallelly correspond to a single VOB or cell. Each link information records "last recorded/modified time (date) information 2061 of corresponding link information". Also, each link information records "drive manufacturer group ID information (ID of a group formed by a plurality of manufacturers) 2034 of a drive manufacturer group that can use specific information in association with the corresponding link information" or "drive manufacturer ID information (drive manufacturer name or the like) 2035 of a drive manufacturer that can use specific information in association with the corresponding link information", and the manufacturer name that can use the corresponding link information can be detected from this information.

(3) A method of obviating the need for manufacturer ID assignment in the specific organization:

An example will be explained with reference to

FIGS. 13A to 13C.

Manufacturer group ID information 2034, drive  
manufacturer ID information 2035, and model information  
2073 (e.g., the oldest model that can use specific  
5 information) indicating models which can use specific  
information are recorded as text information.

Furthermore, in order to cope with identical  
manufacturer names (related companies and the like),  
the link information further contains "additional  
10 information 2037 that pertains to this link information  
that a drive manufacturer can set", and confusion can  
be avoided by setting, e.g., a password. As a text  
information recording method, "ID information 2033 of  
a character code for drive manufacturer use" (e.g., JIS  
15 code ID or the like) is set in the link information.

FIGS. 14A to 14C summary other embodiments which  
pertain to a method of setting "drive manufacturer  
ID information" according to the present invention.

FIG. 12 shows common information, specific  
20 information, and link information recorded on the  
information recording medium, and schematically shows  
links between common information 2001 and specific  
information 2002. An example of a method of linking  
common information 2001 and specific information 2002  
25 will be explained in detail below. Information that  
pertains to a link pattern with respect to each  
specific information 2002 is recorded in the column

of "information 2041 that pertains to the link pattern of specific information associated with this link information" in link information 2003, as shown in FIG. 13A.

5 In the embodiment of the present invention, there are four different link patterns as follows.

(1) Link Pattern A: Call Process from External Program/specific Information Side

10 This pattern uses the processing method shown in FIG. 15. That is, object information 2007 complying with standards in common information 2001 complying with standards is directly used from management/control information 2006 side that can be used by only a specific manufacturer. Since each object information  
15 is managed by video object information 1077 side, information 2006 calls video object information 1107 in practice. As another method, a method of calling cell playback information 1108 as a display unit or PGC control information 1103 that indicates continuous  
20 playback programs is available.

Examples of the method of using this pattern are as follows.

•Management information 2006 that can be used by only a specific manufacturer systematically manages  
25 video information, still picture information, and audio information in all of a plurality of information recording media (optical discs 1001) or a whole

information recording medium having a plurality of recording layers like a multi-disc pack or multi-layered disc, so as to systematically manage PGC control information 1103, cell playback information 1108, and video object information 1107 (information of each recording layer) which are managed in units of layers.

•Program recording reservation information is provided to management/control information 2006 side that can be used by only a specific manufacturer, and information obtained by video recording using that reservation information is recorded as common information 2001 complying with standards (recorded video information is recorded as video object 1012, and management information that pertains to the video information is recorded in management/control information 2005 complying with standards).

•Query information (tree structure information with a large number of layers, keyword query information, and the like) for video information or a huge number of pieces of still picture information recorded is provided to management/control information 2006 side that can be used by only a specific manufacturer, and required video information or still picture information recorded in video objects 1012 or picture objects 1013 is retrieved by search and displayed.

Management/control information 2006 that can be

used by only a specific manufacturer shown in FIG. 15 has information contents for implementing functions associated with basic functions, which are specified by the standards associated with common information 2001.

5 However, the present invention is limited to such specific contents, and management/control information 2006 may be used as an external component for specific external application program 2110. For example, information of picture objects 1013 or video objects  
10 1012 may be pasted in a portion of a document created on document creation software, or may be similarly pasted in presentation software. Furthermore, an application program having a function of extracting some data in video information in video objects 1012,  
15 automatically converting the extracted data into CG (computer graphics) data using, e.g., an edge extraction technique, and animating that CG data as the user wants using, e.g., a morphing technique can be created using the technique of the present invention.

20 (2) Link Pattern B: Partial Exchange Process

This pattern uses the processing method shown in FIG. 16. That is, information obtained by appending information, which has information contents similar to, e.g., VOB 1403 and cell 1443 and correspond to an  
25 original function, to object information 2007 complying with standards with the structure shown in FIGS. 3A to 3J is recorded in "expanded video object information

2115" and "expanded cell playback information 2114".  
By selecting link information 2003 later, VOB 1403 and  
cell 1443 are replaced by the alternative (exchange)  
information in specific information 2002 that can be  
5 used by only a specific manufacturer upon playing back  
and displaying information.

Examples of applications using this processing  
method are as follows.

•Recording Format Conversion of Object Information

10 In the DVD Video specifications, the recording  
format of video information is limited to "MPEG1" or  
"MPEG2". For example, when information recorded in the  
DV (digital video) format is recorded with the data  
structure shown in FIGS. 3A to 3J, video information  
15 converted into the MPEG2 format is recorded (this  
information is recorded in video objects 1012 shown in  
FIG. 16), and original video information in the DV  
format is also recorded as another file in computer  
data area 1008 shown in FIG. 1C. This information  
20 serves as specific object information (specific  
contents information) 2008 that can be used by only  
a specific manufacturer shown in FIG. 16. Furthermore,  
management/control information which pertains to this  
video information in the DV format is recorded as  
25 another file in computer data area 1008, and is used as  
management/control information 2006 that can be used by  
only a specific manufacturer.

Upon playback, an information playback apparatus of a general manufacturer plays back video information recorded in the MPEG2 format in video objects 1012 shown in FIG. 16. By contrast, an information playback apparatus of a specific manufacturer can play back original video information in the DV format, which is recorded in specific object information (specific contents information) 2008 that can be used by only a specific manufacturer. In general, since video information in the DV format has higher image quality than MPEG2 information, a technique unique to the specific manufacturer can be provided.

The same applies not only to video information but also to still picture information. That is, picture objects 1013 shown in FIG. 16 are recorded in the "MPEG2 I-picture format". Still picture information in the bitmap or JPEG format captured by a digital camera is recorded in picture objects 1013 shown in FIG. 16 after format conversion. At the same time, an original picture in the JPEG format is recorded in specific object information (specific contents information) 2008 that can be used by only a specific manufacturer. The information playback apparatus of the specific manufacturer can play back the original picture in the JPEG format with higher resolution (higher image quality) using link information 2003.

•Variable Speed Playback

Cell playback information 1108 shown in FIG. 16 records information for normal playback speed alone. For example, upon making FF (fast playback) or FR (fast  
5 rewind) at double or quadruple speed, frame-decimated playback must be designated. Information indicating a playback procedure corresponding to FF or FR is recorded in advance in cell playback information 2114,  
10 and only an information playback apparatus of a specific manufacturer can achieve FF or FR playback using link information 2003.

•After-recording Insertion Process

When audio information is overwritten by after recording while playing back video information already  
15 recorded in video objects 1012 shown in FIG. 16, only the audio information to be additionally recorded is recorded in audio objects 1014 in common information 2001 complying with standards. After that, as  
20 information that replaces the corresponding information in cell playback information 1108 used for playing back the video information already recorded in video objects 1012, information indicating the mechanism for  
25 simultaneously playing back the video information in video objects 1012 and after-recorded information in audio objects 1014 is created, and is recorded in expanded cell playback information 2114 in specific information 2002 that can be used by only a specific

manufacturer. Only an information playback apparatus  
manufactured by the specific manufacturer can  
simultaneously play back and output the aforementioned  
video information and after-recorded audio information  
5 using expanded cell playback information 2114.

•Video Information Display After Special Edit

Common information 2001 complying with standards  
does not contain any special edit information for video  
information. For example, when the user wants to  
10 execute "fade-in" and "chromakey" special edit  
processes for VOB 1404 in FIG. 3D, management/control  
information is created by appending "fade-in" and  
"chromakey" special edit process information contents  
to management/control information corresponding to VOB  
15 1404 in FIG. 3D contained in video object information  
1107 in FIG. 16, and is recorded in expanded video  
object information 2115. An information playback  
apparatus manufactured by the specific manufacturer  
reads the corresponding information recorded in  
20 expanded video object information 2115, and displays  
and outputs video information which has undergone the  
special edit processes. Note that the special edit  
information is described in the EDL format in expanded  
video object information 2115.

(3) Link Pattern C: Specific Information

Insertion Process

This pattern uses the processing method shown in

FIG. 16. For example, assume that an information playback apparatus manufactured by a general manufacturer plays back in the order of cell 1441 → cell 1442 → cell 1443, as shown in FIG. 3G. By contrast, a specific manufacturer records cell\* in expanded cell playback information 2114 shown in FIG. 16, and designates its insertion location to be "immediately after cell 1442" in link information 2003. An information playback apparatus manufactured by the specific manufacturer can play back PGC 1446 shown in FIG. 3H in the order of "cell 1441 → cell 1442 → cell\* → cell 1443" using link information 2003.

As an example, CM automatic insertion using this method may be attained.

#### (4) Link Pattern D: Function Expansion Process

This pattern uses the processing method shown in FIG. 17, and an original expanded function is directly appended to video object information or cell. Examples of this pattern are as follows.

##### •Parental Lock/Security Function

For example, a security control or parental lock function using password setting is provided to only VOB 1404 in FIG. 3D. This password information is recorded in expanded video object information 2115 shown in FIG. 17.

##### •Small Window Simultaneous Display Function

For example, expanded function information which

allows only cell 1442 in FIG. 3G to make small window display, and can display another video information parallel to the small window display is provided to expanded cell playback information 2114 shown in FIG. 17.

•Displayed Picture Characteristic Improving Function

In video information recorded by, e.g., a camcorder, playback pictures are often dark or fogged or have poor color tone due to backlight or insufficient illumination. Parameters such as "darkness adjustment", "color tone adjustment", and the like are recorded in expanded video object information 2115 in FIG. 17, and parameters for improving picture characteristics are set upon editing after video recording. An information playback apparatus of a specific manufacturer corrects the picture characteristics according to the parameter values using link information upon displaying pictures.

•Location Designation Information Upon Recording/playback Which Can be Set by User

For example, when the location the user watched last upon previous playback is recorded in expanded PGC control information 2113 in FIG. 17, the user can play back information from that location upon next playback.

The information recording medium (optical disc 1001) records information in a plurality of contents

(PTT 1407, PTT 1408, and the like shown in FIG. 3C). Also, the information recording medium (optical disc 1001) records common information 2001 complying with standards and specific information 2002 that can be  
5 used by only a specific manufacturer in units of contents. Furthermore, the information recording medium (optical disc 1001) records link information 2003 indicating the relationship between common information 2001 complying with standards and specific  
10 information 2002. Using a category ID to be described below, different functions can be implemented in units of contents.

FIGS. 18A and 18B show the contents of function information (category ID) 2040 which pertains to  
15 specific information in information of the link information shown in FIG. 13A, and is common to a plurality of companies. FIGS. 18A and 18B show a list of category IDs of company A as an example. The common function contents and link pattern symbols shown in  
20 FIGS. 18A and 18B match the contents described in "<<4>> Link Pattern".

As shown in FIGS. 18A and 18B, the characteristic feature of the present invention lies in that the manufacturer names of information recording/playback  
25 apparatuses or information playback apparatuses that can use contents vary depending on the information contents (PTT 1407 (one type of contents), PTT 1408

(another type of contents) in FIG. 3C) recorded in the information recording medium (optical disc 1001), and different corresponding category IDs can be set. As a result, a category ID that can apply a parental lock to the entire adult video movie, and can cancel the parental lock of only a portion children are free to watch can be set, thus allowing control in terms of discipline. In this case, when category IDs are set depending on the recorded contents, the present invention can greatly contribute to wholesome upbringing of young people.

When only a plurality of specific manufacturers implement a specific function according to their agreement, function information (category ID) 2040 which pertains to specific information and is common to a plurality of companies is effectively used. For example, a case will be examined below wherein companies A, B, C, and D conclude agreements with each other to be able to commonly use common functions other than category IDs 6, 9, and 10. The common functions other than category IDs 6, 9, and 10 shown in FIGS. 18A and 18B can be used by not only company A but also by companies B, C, and D according to FIGS. 18A and 18B. Therefore, company B searches drive manufacturer IDs 2035 in link information shown in FIG. 13A for link information that describes company A, and checks if that link information includes category IDs 2040 = 1, 2,

4, 7, or 12. If such category IDs are found, company B uses the corresponding functions commonly to company A. This means that drive manufacturers that can use contents vary depending on the recorded contents, as in the above description.

Note that companies A, B, C, and D may be considered as either manufacturers or distributors of information recording/playback apparatuses.

A method of checking influences on link information set by an information playback apparatus of the self company after contents recorded on a given information recording medium (optical disc 1001) have changed by an edit process using an information recording/playback apparatus (recorder) of another company will be explained below.

FIGS. 19A to 19F show the internal data structure of edit control information 1023 shown in FIG. 1E.

When data in audio & data area 1009 shown in FIG. 1C has been edited (including addition of new data), history information that pertains to an edit process (addition of new data) must be recorded in edit history information 2141 shown in FIG. 19B. As edit history information 2141, information 2149 that pertains to detailed contents of edit histories, edit (additional recording or change) date/time information 2144, information 2145, and information 2146 are recorded. In an embodiment shown in FIG. 19C,

date/time information 2145 and information 2146 of the second and third latest edit processes are recorded together with date/time information 2144 of the latest edit process.

5           A plurality of pieces of link information 2003 having the data structure shown in FIGS. 13A to 13C are recorded on the information recording medium (optical disc 1001), as shown in FIG. 20D. A case will be explained below wherein, for example, link information  
10       #β 2164 is used. One link information #β 2164 records various kinds of information shown in FIG. 20E or classification items 2020 in FIGS. 13A to 13C, and especially, classification item 2020 of "time informa-  
15       tion 2027 that pertains to this link information" of those information records "last recording time (date) information 2061 of this link information", as shown in FIG. 20F (or FIG. 13C). Last recording time (date) information 2061 of this link information is played  
20       back to read the date and time when link information #β 2164 was created or edited/changed last. This date/time is compared with the latest editing date/time of information in audio & video data area 1009 shown in FIG. 19C. If the latter date is equal to or earlier than the former date, it is determined that link  
25       information #β 2164 was created or changed (edited) at the same time as or after the latest edit process of information in audio & video data area 1009. In this

00934827.0823304  
T08280"/284E660

case, link information #β 2164 can be used without any problem.

Conversely, when information in audio & video data area 1009 was edited after link information #β 2164 had been created or changed (edited) (when "date/time information 2144 of the latest edit process shown in FIG. 19C" is later than "last recording time (date) information 2061 of link information shown in FIG. 20F", since information in audio & video data area 1009 was changed after link information #β 2164 had been created or changed (edited), it may not be possible to use link information #β 2164. In management/control information 2011 (FIG. 12) in common information 2001 complying with standards, as shown in FIGS. 20A to 20C, all of PGC control information 1103, cell playback information 2162 to information 2164, and video object information 2167 to information 2169 record their last creation/change (edit) date/time information 2151 to information 2159. Therefore, in the aforementioned case, locations in common information 2001 complying with standards, which are designated by link information #β 2164, are checked. In an embodiment shown in FIGS. 20A to 20F, since link information #β 2164 designates video information #2 2168 as a link source, last creation/change (edit) date/time information 2158 of video object #2 2168 is played back and compared. When last recording time (date) information 2061 of link

information #β 2164 is equal to later than last  
creation/change (edit) date/time information 2158 of  
video object information #2 2168, it is determined that  
locations other than video object information #2 2168  
5 were edited, and this link information #β 2164 can be  
used without any problems. By contrast, when last  
recording time (date) information 2061 of link  
information #β 2164 is earlier than last creation/  
change (edit) date/time information 2158 of video  
10 object information #2 2168, since the contents of  
video object information #2 2168 were changed after  
link information #β 2164 had been set, it may not be  
possible to use link information #β 2164. In such case,  
the information recording/playback apparatus detects  
15 changed locations of video object information #2 2168  
and a method of changing/correcting specific  
information 2002 that can be used by only a specific  
manufacturer corresponding to link information #β 2164,  
using "correction content automatic inspection  
20 information 2042 for automatically changing/correcting  
contents of specific information that can be used by  
only a specific manufacturer in correspondence with a  
change in contents of common information complying with  
standards" shown in FIG. 13B, and then automatically  
25 changes/corrects specific information that can be used  
by only a specific manufacturer.

On the other hand, when contents of video object

information #2 2168 have been changed or edited, its  
last creation/change (edit) date/time information 2158  
is changed in correspondence with that change/edit date,  
and the contents of specific information that can  
5 be used by a specific manufacturer as each of link  
destinations of corresponding link information #β 2164,  
information #γ 2165, and #δ 2166 are changed and  
corrected. In addition, date/time information of each  
"last recording time (date) information 2061 of link  
10 information" is also changed.

Since the information recording medium (optical  
disc 1001) shown in FIG. 1A has high portability, it is  
likely to be used in turn in a plurality of information  
recording/playback apparatuses. For this reason,  
15 after link information 2164 is set by an information  
recording/playback apparatus of company A, if an  
information recording/playback apparatus of company B  
changes and edits a link source portion in common  
information 2001 complying with standards, link  
20 information 2164 can no longer be used. As described  
above, the characteristic features of the present  
invention lie in that:

(1) "last change/correction (edit) time  
information" is recorded in both link information  
25 2164 and common information 2001, and these pieces of  
time information are compared before link information  
2164 is used, so as to confirm the validity of link

information; and

(2) "correction content automatic inspection information 2042" is recorded in advance in link information so as to allow automatic correction of the contents of specific information 2002 even when common information 2001 complying with standards has been changed (edited).

There are four different embodiments of a method of setting a link source (a designation location in common information complying with standards) corresponding to each link information in the present invention, as shown in FIGS. 21A to 21D. (The respective setting methods are set with symbols (A) to (D).)

In one method, a bit sequence (e.g., all "1"s for 8 bytes) which never exists in common information 2001 complying with standards is inserted at an arbitrary position and is used as a "tag" for setting a designation location, and the "tag" inserted position is defined as the designation location of the link source. An information playback apparatus which does not use link information skips data from the "tag" information to inserted data size information that follows immediately after the "tag" information, thus removing the influence of link information. A method of allocating "pointer information" behind "tag" information", and designating corresponding link

information (its ID information or link information  
number 2031) in this "pointer information" ((A) of  
FIG. 21A) and a method of directly allocating link  
information 2003 behind "tag" information ((B) of  
5 FIG. 21B) are available. In the latter method, a  
plurality of link information are distributed in common  
information 2001 complying with standards. The methods  
of these two embodiments are suitable for link pattern  
A (call process from external program/specific  
10 information side) shown in FIG. 15.

As tag information, bit sequence information (e.g.,  
all "1"s for 8 bytes) which never exists in common  
information 2001 is formed and inserted in common  
information 2001, and "pointer information" or "link  
15 information" is allocated immediately after that bit  
sequence. A drive (information playback apparatus)  
manufactured by a drive manufacturer that does not  
use link information checks the pointer size or link  
information size described immediately after this tag  
20 information to skip that range.

By contrast, in case of link pattern B (partial  
exchange process) or link pattern C (specific  
information insertion process) shown in FIG. 16 or link  
pattern D (function expansion process) shown in FIG. 17,  
25 the designation range of a link source is determined  
to be PGC control information 1103, cell playback  
information 1108, and video object information 1107.

(In link pattern A (call process from external program/specific information side) shown in FIG. 15 as well, the link source designation range may be fixed.) In such case, setting methods (C) and (D) shown in  
5 FIGS. 21C and 21D are suitably used.

In setting method (C), information recording columns for designating link information (its ID information or link information number 2031) are formed in advance in PGC control information 1103,  
10 cell playback information 1108, and video object information 1107.

A method of setting the designation location of link information without changing common information 2001 complying with standards (without exerting any  
15 load on common information 2001) is method (D), in which link information contains information that pertains to the link source and link range.  
"Number 2044 of link designation locations in common information complying with standards", and "first  
20 priority link designation location information 2045 in common information complying with standards" to "second priority link designation location information 2046 in common information complying with standards" shown in  
FIG. 13B are information items set assuming a case that  
25 uses method (D).

A file structure having neither link information 2003 nor specific information 2002 corresponding to

an expansion function will be explained first.

5 All pieces of information are recorded in data area 1004 in FIG. 1B in units of files, and the relationship between the data and files are managed by the directory structure, as shown in FIG. 2.

10 A plurality of subdirectories 1451 are contained within root directory 1450 to allow easy classification in units of recorded file contents. In FIG. 2, data files that pertain to computer data recorded on computer data areas 1008 and 1010 shown in FIG. 1C are recorded under subdirectory 1457 for computer data storage, and audio & video data recorded on audio & video data area 1009 are recorded under rewritable video title set RW\_VTS 1452. On the other hand, upon  
15 copying video information recorded on a DVD Video disc to the disc shown in FIG. 1A, data are copied under video title set VIDEO\_TS 1455 and audio title set AUDIO\_TS 1456.

20 Control information 1011 in FIG. 1D is recorded as a single file for rewritable video management data. In FIG. 2, this information has file name RW\_VIDEO\_CONTROL.IFO. Furthermore, identical information is also recorded as backup information with file name RW\_VIDEO\_CONTROL.BUP.

25 In FIG. 2, all video information data that belong to video objects 1012 shown in FIG. 1D are recorded as a video objects file with file name RW\_VIDEO.VOB.

That is, all video information data that belong to video objects 1012 shown in FIG. 1D are continuously linked in a single VTS (video title set 1402), as shown in FIG. 3B, and are continuously recorded in a single file named "video objects file". (In other words, all data are recorded together in a single file without dividing a file in units of PTTs (part\_of\_title) 1407 and 1408.)

All still picture information data that belong to picture objects 1013 are recorded together in a picture objects file with file name RW\_PICTURE.POB. Picture objects 1013 contain a plurality of pieces of still picture information. A digital camera adopts a format in which each still picture is recorded as an independent file, but the embodiment of the present invention is characterized in that all still pictures contained in picture objects 1013 are continuously linked in a format similar to that shown in FIGS. 3A to 3J, and are recorded together in a single picture objects file with file name RW\_PICTURE.POB.

Likewise, all pieces of audio information that belong to audio objects 1014 are recorded in a single audio objects file with file name RW\_AUDIO.AOB, and all pieces of thumbnail information that belong to thumbnail objects 1016 are recorded in a single thumbnail objects file with file name RW\_THUMBNAIL.TOB.

Note that the video objects file, picture objects

file, audio objects file, and thumbnail objects file are handled as AV file 1401.

5 Rewritable additional information 1454 (not shown in FIGS. 1A to 1F) that can be used upon recording/ playing back video information can be simultaneously recorded. That information is recorded as a single file, which has file name RW\_ADD.DAT in the embodiment in FIG. 2.

10 An embodiment of the present invention that pertains to the allocation of link information will be explained below while comparing with the file structure shown in FIG. 2.

15 An embodiment in which link information 2003 is allocated in common information 2001 shown in FIG. 22A will be explained first. In case of this embodiment, link information 2003 is recorded together in two files, i.e., control information 1011 in FIG. 2 = RW\_VIDEO\_CONTROL.IFO (rewritable video management data) and backup data of control information 1011 =  
20 RW\_VIDEO\_CONTROL.BUP (rewritable video management data backup). As detailed recording locations in these two files, all pieces of link information are recorded together at the recording location of link information 2003 (FIG. 19B) in edit control information 1023 shown  
25 in FIG. 1E. In link information 2003, a plurality of pieces of link information 2163 to 2167 are continuously allocated, as shown in FIG. 20D.

An embodiment in which link information is allocated in specific information 2002 shown in FIG. 22B means a state wherein link information is recorded together with specific information 2002 in common file 2181 = RW\_ADD.DAT (a kind of rewritable additional information 1454) that records specific information, as shown in, e.g., FIG. 24.

In an embodiment shown in FIG. 22C in which all pieces of link information are allocated together at a unique location, unique link information like 2171 = RW\_LINK.DAT is set under subdirectory 1451 of rewritable video title set RW\_VTS 1452, as shown in FIG. 23, and the respective pieces of link information 2163 to 2167 are allocated at neighboring locations, as shown in FIG. 19D. This unique link information like 2171 = RW\_LINK.DAT is located as a kind of rewritable additional information 1454 = RW\_ADD.DAT (rewritable video additional information).

An embodiment in which groups of link information to be used in units of drive manufacturers are allocated together shown in FIG. 22C means a file structure shown in FIG. 23. That is, subdirectories (dedicated subdirectory 2185 for company A, and dedicated subdirectory 2186 for company B) in units of drive manufacturers are created under root directory 1450, and link information files in units of drive manufacturers such as dedicated link information 2191

for company A = LINKINFO\_A.IFO and the like are set.  
In the link information file, the respective pieces  
of link information 2163 to 2167 are allocated and  
recorded at neighboring locations, as shown in FIG. 19D.

5           FIG. 23 shows an embodiment of a method of  
allocating specific information 2002 that can be used  
by only a specific manufacturer. Basically, specific  
information is recorded in subdirectory 1451 of  
rewritable video title set RW\_VTS 1452 where common  
10   information 2001 complying with standards is recorded.  
As shown in FIG. 23, directories for recording specific  
information 2002 are separated in units of drive  
manufacturers like directory 2173 for specific  
information of company A = RW\_ADD\_A and directory 2174  
15   for specific information of company B = RW\_ADD\_B.  
Since the directories are separated, as shown in  
FIG. 23, specific information 2176 and information 2177  
of company A can be prevented from being destroyed upon  
changing, e.g., specific information of company B.  
20   Also, as shown in FIG. 12, of specific information 2002  
that can be used by only a specific manufacturer,  
management/control information 2006 that can be used  
by only a specific manufacturer is recorded in a file  
of specific management/control information 2176 =  
25   RW\_A\_CONTROL.IFO dedicated to company A in FIG. 23, and  
the contents of specific object information (specific  
contents information) 2008 that can be used by only

a specific manufacturer are recorded in a file of specific object information 2177 = RW\_A\_OBJECT.VOB dedicated to company A in FIG. 23.

FIG. 24 shows another embodiment of a method of allocating specific information 2002 that can be used by only a specific manufacturer in the present invention. This embodiment is characterized in that all pieces of specific information 2002 are recorded together in a single file independently of drive manufacturers of information recording/playback apparatuses that create specific information 2002. Common file 2181 that records specific information has file name RW\_ADD.DAT, and is allocated under rewritable video title set RW\_VTS 1452 as common subdirectory 1451 where another common information 2001 complying with standards is recorded. Common file 2181 that records specific information is a kind of rewritable additional information 1454 = RW\_ADD.DAT (rewritable video additional information) shown in FIG. 2.

Furthermore, FIG. 25 shows still another embodiment of a method of allocating specific information 2002 that can be used by only a specific manufacturer in the present invention. Referring to FIG. 25, specific information 2002 is allocated outside subdirectory 1451 of rewritable video title set RW\_VTS 1452 unlike FIGS. 23 and 24. Subdirectories (dedicated subdirectory 2185 for company A, and dedicated

subdirectory 2186 for company B) are created under  
root directory 1450 in units of drive manufacturers  
of information recording/playback apparatuses for  
recording specific information, and specific  
5 information 2002 is recorded under each subdirectory.  
Of specific information 2002 that can be used by only  
a specific manufacturer shown in FIG. 12, management/  
control information 2006 that can be used by only a  
specific manufacturer is recorded in a file of specific  
10 management/control information 2192 = CONTROLIFO\_A.IFO  
dedicated to company A in FIG. 25, and the contents  
of specific object information (specific contents  
information) 2008 are recorded in a file of specific  
object information 2193 = A\_OBJECT.VOB dedicated to  
15 company A in FIG. 25.

The procedure of a method of playing back and  
displaying link information in the information  
recording/playback apparatus for recording video  
information shown in FIG. 10 will be explained below.

20 An embodiment will be explained while taking as  
an example a case wherein the information recording/  
playback apparatus for recording video information is  
a product of drive manufacturer A. FIGS. 26A and 26B  
show the playback/display procedure in this case.

25 The entire flow charts shown in FIGS. 26A and 26B  
will be explained first.

(ST201) Start-up process of information

recording/reproducing unit 101

Information recording medium (optical disc) 201  
is rotated, and focus/track servo of optical head 202  
is turned on to enable information playback from  
5 information recording medium (optical disc) 201.

(ST202) Store information required for  
recording/playing back video information in memory

System controller (MPU) 1530 controls information  
recording/reproducing unit 101 to read control  
10 information 1011 and link information file 2171  
(FIG. 23) from information recording medium (optical  
disc) 201, and temporarily stores them in its internal  
semiconductor RAM.

(ST203) Extract process of link information  
15 created by company A

System controller (MPU) 1530 searches all pieces  
of link information in link information file 2171  
temporarily stored in its internal semiconductor RAM  
and extracts link information whose drive manufacturer  
20 ID information 2035 (FIG. 13A) corresponds to company A.

(ST204) Process for confirming presence/absence  
of editing of common information done after setting  
times of all pieces of link information corresponding  
to company A

25 System controller (MPU) 1530 checks last recording  
time (date) information 2061 (FIG. 13C) of each link  
information corresponding to company A in link

information file 2171 temporarily stored in its  
internal semiconductor RAM, and compares it with  
date/time information 2144 (FIG. 19C) of the latest  
edit process (including addition of new data) to common  
5 information, so as to check if the common information  
has been edited after the setting times of all the  
pieces of link information corresponding to company A.

(ST205) Determination

It is determined whether or not the common  
10 information has been edited after the creation/change  
times of all the pieces of link information  
corresponding to company A.

(ST206) Confirmation process of last edit time of  
corresponding location in common information designated  
15 by link information of company A

System controller (MPU) 1530 extracts last  
recording time (date) information 2061 (FIG. 13C) of  
each link information corresponding to company A and  
corresponding locations (link source designation  
20 location and designation range 2026 in FIGS. 13B and  
13C) in common information designated by each link  
information from link information file 2171 temporarily  
stored in its internal semiconductor RAM.

System controller (MPU) 1530 extracts a plurality  
25 of pieces of last creation/change date/time information  
2151 to 2159 (FIGS. 20A to 20C) of link source  
designation locations in common information from

control information 1011 temporarily stored in its  
internal semiconductor RAM.

(ST207) Determination

5 It is determined whether or not the link source  
designation locations in the common information have  
been edited after the creation/change times of all the  
pieces of link information corresponding to company A.

(ST208) Specific information correction process  
corresponding to link information set before last edit  
10 time of link source

System controller (MPU) 1530 automatically detects  
changes in link source designation location using  
correction contents automatic inspection information  
2042 (FIG. 13B) from the link information set before  
15 the last edit time of the link source, and changes the  
contents of the corresponding specific information  
(specific management/control information 2176 and  
specific object information 2177 dedicated to company A  
in FIG. 23) in correspondence with the detected changes.

20 System controller 1530 updates last recording time  
information 2071 (FIG. 13C) of the link information to  
indicate the correction time.

(ST209) Extraction process of link information  
that another company can use and is specified by  
25 category ID

System controller (MPU) 1530 checks category ID  
information 2040 (FIG. 13A) of link information

corresponding to companies other than company A in link information file 2171 temporarily stored in its internal semiconductor RAM.

5       System controller (MPU) 1530 compares usable category IDs stored in advance in its internal semiconductor ROM (information that company A can use in a category ID list of other companies is recorded in advance as in FIGS. 18A and 18B) and category IDs of other companies recorded on information recording medium (optical disc) 201 to extract link information  
10       which is usable by another company.

(ST210) Determination

It is determined whether or not the common information has been edited after the creation/change  
15       time of link information that another company can use and is checked in step ST209.

(ST211) Confirmation process of last edit time of corresponding location in common information designated by link information of another company

20       System controller (MPU) 1530 extracts last recording time (date) information 2061 (FIG. 13C) of each link information usable by another company and corresponding locations (link source designation location and designation range 2026 in FIGS. 13B and  
25       13C) in common information designated by each link information from link information file 2171 temporarily stored in its internal semiconductor RAM.

FOI2007-224550

System controller (MPU) 1530 extracts a plurality of pieces of last creation/change date/time information 2151 to 2159 (FIGS. 20A to 20C) of link source designation locations in common information from control  
5 information 1011 temporarily stored in its internal semiconductor RAM, and checks their time relationship.

For link information of another company which set the corresponding location in the common information designated as a link source last before the last edit  
10 time, specific information 2176 and information 2177 are not corrected unlike step ST208, and are inhibited from being used.

(ST212) Inquiry of user as to whether or not link information is used

15 System controller (MPU) 1530 displays, on display/ input panel 1548 of RTR recorder, an inquiry of user as to whether the original functions of the information recording/playback apparatus (video recorder) for  
20 recording video information are used by utilizing individual usable link information selected by the aforementioned processes or playback/display is made using only common information 2001 complying with standards.

If the user denies use of link information,  
25 information is played back from information recording medium (optical disc) 201 using only common information 2001 complying with standards without using any link

information, and the playback result is displayed on display/input panel 1548 of RTR recorder.

(ST213) Playback/display process using link information and specific information

5           Link source corresponding locations in common information 2001 designated in link information, which is designated by the user in response to the inquiry in step ST212, are extracted by searching the contents of link information file 2171 temporarily stored in the semiconductor RAM in system controller (MPU) 1530.

10           Locations in PGC control information 1103 (FIG. 20A) of the link source designation locations are recorded at other locations in the semiconductor RAM on the basis of control information 1011 temporarily stored in the semiconductor RAM in system controller

15           (MPU) 1530.

          Common information 2001 is played back and displayed in accordance with a PGC (FIG. 20A) to be played back designated by the user, and when the

20           playback location has reached the aforementioned link source designation location, specific information 2002 is called via link information 2003 to play back and display information on display/input panel 1548 of RTR recorder on the basis of the original functions.

25           The flow charts shown in FIGS. 26A and 26B will be described in more detail below. The present invention is characterized by the process (ST204) of checking the

relationship between "last recording time information  
2061 of link information" recorded in link information  
shown in FIG. 13C, and "date/time information 2144  
of the latest edit process (content change/addition/  
5 deletion) of common information 2001" shown in FIG. 19C.  
With this process, whether or not the contents of  
common information 2001 have been changed (edited)  
by an information recording/playback apparatus for  
recording video information of another company after  
10 the corresponding link information had been set last.  
If the contents of common information 2001 have been  
changed (edited), it is checked if the location which  
is designated as a link source by the corresponding  
link information has been changed (edited) (after the  
15 link information was set last) (ST207 and ST210). If  
the edit result adversely influenced link information,  
drive manufacturer ID information 2035 in the link  
information is checked, and

(1) if the link information is the one created by  
20 the self company (company A in the above embodiment),  
changes in location designated as a link source by  
the link information as a result of the edit process  
are automatically detected using correction content  
automatic inspection information 2042 (FIG. 13B) in  
25 the link information, and specific information 2002  
(FIG. 12) is automatically changed in accordance with  
the detection result (ST208 in FIG. 26A); or

(2) if the link information is other than the one created by the self company (company A), the corresponding specific information is inhibited from being used (ST211 in FIG. 26B).

5 In the procedure shown in FIG. 26A, even when drive manufacturer ID 2035 indicates not only the self company (company A in the above embodiment) but also another company, category ID 2040 as function information common to a plurality of companies in association  
10 with specific information is read, and link information the self company (company A) can use is allowed to be used (ST209 in FIG. 26A).

An example of step ST213 in FIG. 26B will be explained below.

15 When the original function is a "search process using query information", query information is recorded in advance in management/control information 2006 (FIG. 12) that can be used by only a specific manufacturer, and the user selects information using  
20 the contents displayed on display/input panel 1548 of RTR recorder (FIG. 10). Video object information #2 2168 (FIG. 20C) in common information 2001 is then selected using link information 2003 on the basis of information extracted from management/control  
25 information 2006 that can be used by only a specific manufacturer in accordance with the user's choice, and is played back and displayed.

On the other hand, when the original function is to execute "variable speed playback" of only a CM location in the recorded information, if cell playback information #c 2164 in FIG. 20B corresponds to a CM portion in the recorded information, expanded cell playback information 2114 (FIG. 16) which records fast playback (FF) information and corresponds to partial exchange process 2121 is recorded in file RW\_A\_CONTROL.IFO (FIG. 23) for specific management/control information 2176 dedicated to company A as management/control information 2006 (FIG. 12) that can be used by only a specific manufacturer via link information #e 2167 in correspondence with that CM portion. When PGC control information 1103 shown in FIG. 20A is played back and displayed, cell playback information #c 2164 is replaced by expanded cell playback information 2114 to play back the CM portion at speed higher than normal speed.

FIG. 27 is a flow chart showing the procedure for simultaneously recording common information 2001, link information 2003, and specific information 2002.

The entire flow chart shown in FIG. 27 will be explained first.

(ST221) Start-up process of information recording/reproducing unit 101

Information recording medium (optical disc) 201 is rotated, and focus/track servo of optical head 202

is turned on to enable information playback from  
information recording medium (optical disc) 201.

(ST222) Creation process of dedicated directory  
for recording specific information on information  
5 recording medium

System controller (MPU) 1530 of an information  
recording/playback apparatus (video recorder) for  
recording/playing back information receives a command  
for simultaneously recording common information, link  
10 information, and specific information from the user.

System controller (MPU) 1530 creates specific  
information directory RW\_ADD\_A 2173 (FIG. 23) for  
company A on the information recording medium (optical  
disc 1001 and optical disc 201) (if that directory is  
15 already present, this process is skipped).

(ST223) Store information required for recording/  
playing back video information in memory

System controller (MPU) 1530 controls information  
recording/reproducing unit 101 to read control  
20 information 1011, link information file 2171 (FIG. 23),  
and a file of specific management/control information  
2176 dedicated to company A from information recording  
medium (optical disc) 201, and temporarily stores them  
in its internal semiconductor RAM.

25 If either link information file 2171 or the file  
of specific management/control information 2176  
dedicated to company A has not been created yet, the

encoder 1554 convert information input from AV input  
1542 into the recording format (MPEG2 or the like)  
complying with standards, and formatter 1556 re-formats  
the converted information into the data structure shown  
5 in FIG. 3F and temporarily stores that information in  
memory 1534 as object information 2007 complying with  
standards.

(ST227) Recording process of object information  
complying with standards and specific object  
10 information on information recording medium

System controller (MPU) 1530 sends a command to  
information recording/reproducing unit 101 to create  
file RW\_A\_OBJECT.VOB for recording specific object  
information 2177 dedicated to company A on the  
15 information recording medium (optical disc 1001 and  
optical disc 201) (if such file already exists, this  
process is skipped).

Information recording/reproducing unit 101  
alternately reads out object information 2007 complying  
20 with standards and specific object information 2008  
from memory 1534 under the control of system controller  
(MPU) 1530 and records them on the information  
recording medium (optical disc 1001 and optical  
disc 201).

25 Object information 2007 complying with standards  
is additionally recorded in a video object file,  
picture object file, or audio object file handled as

AV file 1401 in FIG. 23.

Specific object information (specific contents information) 2008 that can be used by only a specific manufacturer is additionally recorded in specific object information file RW\_A\_OBJECT.VOB 2177 dedicated to company A in FIG. 23.

(ST228) Additional recording process of management/control information 2005 complying with standards

Upon completion of the recording process on the information recording medium in step ST227, system controller (MPU) 1530 collects the added contents according to the recording result in step ST227 with respect to management/control information 2005 complying with standards, and controls information recording/reproducing unit 101 to additionally record additional information in two files RW\_VIDEO\_CONTROL.IFO and RW\_VIDEO\_CONTROL.BUP that record control information 1011 in FIG. 23, thus executing the recording process.

(ST229) Additional recording process of management/control information file that can be used by only specific manufacturer

If file RW\_A\_CONTROL.IFO of specific management/control information 2176 dedicated to company A in FIG. 23 is not present in this process, this file is newly created (if that file already exists, the

creation process is skipped).

System controller (MPU) 1530 collects contents to be additionally recorded in file RW\_A\_CONTROL.IFO of specific management/control information 2176 dedicated to company A on the basis of the recording result of specific object information (specific contents information) 2008 in step ST227, and controls information recording/reproducing unit 101 to additionally record those contents in the file.

(ST230) Addition process of link information

If link information file 2171 in FIG. 23 does not exist in this process, a new link information file is created (if that file already exists, the creation process is skipped).

System controller (MPU) 1530 collects link information contents to be added on the basis of the contents of management/control information 2005 and information 2176 recorded in steps ST228 and ST229, and controls information recording/reproducing unit 101 to record additional information in link information file 2171 RW\_LINK.DAT.

As shown in FIGS. 13A and 13B, the link information to be additionally recorded includes:

- drive manufacturer ID information 2035;
- category ID 2040;
- correction content automatic inspection information 2042 of specific information; and the like.

Date and time information upon setting additional link information in step ST230 is recorded or updated in last recording/change time (date) information 2061 of this link information shown in FIG. 13C.

5           The flow chart shown in FIG. 27 will be described in more detail below. An embodiment will be exemplified wherein digital video information recorded on a DV (digital video tape) or a still picture in the JPEG format, which is sensed by digital camera 1543  
10           (FIG. 10), is recorded on information recording medium (optical disc) 201. In steps ST224 and ST227 in FIG. 27, the digital video information in the DV format or still picture information in the JPEG format is recorded in file RW\_A\_OBJECT.VOB for recording specific  
15           object information 2177 dedicated to company A in FIG. 23, and management/control information that pertains to the recorded information is recorded in recording file RW\_A\_CONTROL.IFO of specific management/control information 2176 dedicated to company A (ST229).

20           Parallel to this recording process, as shown in steps ST226 and ST227 in FIG. 27, the digital video information in the DV format or still picture information in the JPEG format is converted into digital video information in the MPEG2 format or still  
25           picture information of the MPEG2 I-picture format as the recording format that complies with the DVD standards by V encoder 1553, SP encoder 1555, A encoder

1554, and formatter 1556 in FIG. 10, and is recorded as  
object information 2007 (FIG. 12) complying with  
standards in a video objects file, picture objects file,  
or audio objects file handled as AV file 1401 in  
5 FIG. 23. At the same time, management/control  
information 2005 that pertains to the recorded  
information is recorded in two files  
RW\_VIDEO\_CONTROL.IFO and RW\_VIDEO\_CONTROL.BUP  
associated with control information 1011 (ST228).

10 Upon playback/display, the user selects  
information to be played back, and one of object  
information 2007 complying with standards and specific  
object information (specific contents information) 2008  
that can be used by a specific manufacturer is played  
15 back and displayed on display/input panel 1548 of RTR  
recorder in accordance with user's choice.

FIG. 28 is a flow chart showing the method  
of appending link information 2003 and specific  
information 2002 to common information 2001 already  
20 recorded on the information recording medium.

The entire flow chart shown in FIG. 28 will be  
explained first.

(ST233) Start-up process of information  
recording/reproducing unit 101

25 Information recording medium (optical disc) 201  
is rotated, and focus/track servo of optical head 202  
is turned on to enable information playback from

information recording medium (optical disc) 201.

(ST234) Store information required for recording/playing back video information in memory

System controller (MPU) 1530 controls information  
5 recording/reproducing unit 101 to read control  
information 1011 and link information file 2171  
(FIG. 23) from information recording medium (optical  
disc) 201, and temporarily stores them in its internal  
semiconductor RAM.

10 (ST235) Receive original function contents and  
original function setting range designation information  
by user

The user selects the original function of the  
information recording/playback apparatus for recording  
15 video information (video recorder) via the user  
interface using display/input panel 1548 of RTR  
recorder, and designates the range for designating that  
original function.

System controller (MPU) 1530 interprets the  
20 original function contents designated by the user using  
control information 1011 as management/control  
information 2005 complying with standards, which is  
temporarily stored in its internal semiconductor RAM.

(ST236) Information addition process to  
25 management/control information 2006 that can be used by  
specific manufacturer

System controller (MPU) 1530 creates addition

information to management/control information 2006 that  
can be used by only a specific manufacturer on the  
basis of the original function contents and range  
designated by the user, and controls information  
5 recording/reproducing unit 101 to additionally record  
that information in specific management/control  
information file 2176 RW\_A\_CONTROL.IFO dedicated to  
company A shown in FIG. 23.

(ST237) Addition process of link information

10 If link information file 2171 shown in FIG. 23  
does not exist in this process, a new link information  
file is created (if such file already exists, the  
creation process is skipped).

System controller (MPU) 1530 collects link  
15 information contents to be added on the basis of the  
contents of control information 1011 temporarily stored  
in memory 1534 in step ST234 and management/control  
information 2006 that can be used by only a specific  
manufacturer, which is additionally recorded in step  
20 ST236, and controls information recording/reproducing  
unit 101 to record the additional information in link  
information file 2171 RW\_LINK.DAT.

As shown in FIGS. 13A and 13B, the link  
information to be additionally recorded includes:

- 25
- drive manufacturer ID information 2035;
  - category ID 2040;
  - correction content automatic inspection

information 2042 of specific information; and the like.

Date and time information upon setting additional link information in step ST237 is recorded or updated in last recording/change time (date) information 2061 of this link information shown in FIG. 13C.

The flow chart shown in FIG. 28 will be described in more detail below. An embodiment of parental lock or security setup by setting a password in, e.g., cell playback information #c 2164 in FIG. 19B will be explained below. A parental lock or security setup instruction at that location is received from the user (ST235 in FIG. 28).

Expanded cell playback information 2114 (FIG. 16) which is additionally recorded with password information and corresponds to partial exchange process 2121 is recorded in file RW\_A\_CONTROL.IFO (FIG. 23) for specific management/control information 2176 dedicated to company A as management/control information 2006 (FIG. 12) that can be used by only a specific manufacturer via link information #e 2167 in correspondence with that location (ST236). Upon playing back and displaying PGC control information 1103 shown in FIG. 20A, cell playback information #c 2164 is replaced by expanded cell playback information 2114. When the display timing of this portion has been reached, a password inquiry message for the user is displayed on display/input panel 1548 of RTR recorder. Only when

the user inputs a correct password without any errors, this portion can be played back and displayed.

FIG. 29 is a flow chart that pertains to processes upon editing common information 2001.

5           The entire flow chart shown in FIG. 29 will be explained first.

(ST241) Start-up process of information recording/reproducing unit 101

10           Information recording medium (optical disc) 201 is rotated, and focus/track servo of optical head 202 is turned on to enable information playback from information recording medium (optical disc) 201.

(ST242) Store information required for recording/playing back video information in memory

15           System controller (MPU) 1530 controls information recording/reproducing unit 101 to read control information 1011 and link information file 2171 (FIG. 23) from information recording medium (optical disc) 201, and temporarily stores them in its internal semiconductor RAM.

20

(ST243) Extraction process of link information created by company A

          System controller (MPU) 1530 extracts link information which includes drive manufacturer ID information 2035 (FIG. 13A) corresponding to company A by searching all pieces of link information in link information file 2171 temporarily stored in its

25

TOP SECRET

internal semiconductor RAM.

(ST244) Receive information of edit contents in common information from user

5 The user designates information that pertains to edit contents in common information 2001 complying with standards by the information recording/playback apparatus for recording video information via the user interface using display/input panel 1548 of RTR recorder. System controller 1530 receives that  
10 information.

System controller (MPU) 1530 determines a practical method for the edit contents designated by the user using control information 1011 as management/control information 2005 complying with standards,  
15 which is temporarily stored in its internal semiconductor RAM.

(ST245) Execute edit process in common information

System controller (MPU) 1530 edits common  
20 information 2001 complying with standards on the basis of the processing method determined in step ST244, and controls information recording/reproducing unit 101 as needed to record information on information recording medium (optical disc) 201.

25 (ST246) Update process of last creation/change date/time information in management/control information complying with standards

System controller (MPU) 1530 changes the contents of management/control information 2005 complying with standards on the basis of the edit process done in step ST245, and controls information recording/reproducing unit 101 to rewrite the contents of files RW\_VIDEO\_CONTROL.IFO and RW\_VIDEO\_CONTROL.BUP associated with control information 1011 shown in FIG. 23.

System controller (MPU) 1530 simultaneously executes update processes of last creation/change date/time information (information that pertains to the changed portion upon editing of 2151 to 2159 in FIGS. 20A to 20C) and date/time information 2144 of the latest edit process shown in FIG. 19C, which pertain to the aforementioned edit process.

(ST247) Change process of link information contents of company A that pertains to edit process

System controller (MPU) 1530 finds link information which is influenced by the edit process of common information 2001 done in step ST245 by search from those including drive manufacturer ID information 2035 (FIG. 13A) corresponding to company A, which are extracted in step ST243, changes the corresponding portion of specific information 2002 designated as a link destination of that link information in correspondence with the edit process, and controls information recording/reproducing unit 101 to change

and record that change result in the contents of files 2176 and 2177 in directory 2173 for specific information of company A.

System controller (MPU) 1530 updates and records  
5 last recording/change time information 2061 (FIG. 13C)  
of each link information corresponding to company A  
irrespective of the presence/absence of influences of  
the edit process.

The flow chart shown in FIG. 29 will be described in more detail below. As described previously, assuming a case wherein information recording medium (optical disc) 201 is used by an information recording/playback apparatus of another company after common information 2001 has been edited, a recording process for making link information usable in such a case is required. That is, the update process of "last creation/change date/time information 2151 to information 2159" (FIGS. 20A to 20C) of portions that have been changed by the edit process, and "date/time information 2144 of the latest edit process" as a whole is executed (ST246). At the same time, "last recording time information 2061" in link information is updated, and the contents of the corresponding specific information are changed (ST247).

25           Applications of the present invention will be  
explained below.

The present invention can be applied to a program

09437 0301  
10E220 224E560

(software) recording scheme in an information processing apparatus, which records program (software) information described in various program languages such as "C", "Visual C", "JAVA", and the like on an information recording medium, reproduces the program (software) information from that information recording medium, and makes an implementation process according to the reproduced program (software) contents. That is, an information recording scheme (description rule of a program language) for recording information on the information recording medium can be applied to that which is commonly standardized and recognized among a plurality of manufacturers which manufacture arithmetic processing apparatuses for reproducing a program (software) from the information recording medium, and making an implementation process according to the reproduced program (software) contents.

In the arithmetic operation field (computer field), an arithmetic operation program is described according to rules (standards) of various program languages such as "C", "Visual C", "JAVA", and the like. If a command that violates such rules of the program language is described in a program, it is rejected as an error.

For example, processing functions that can be controlled by programs which pertain to a "communication protocol", "graphical user interface", "image processing function", and the like are

considerably limited by the program languages used.  
That is, differentiated and original functions  
cannot be provided. By contrast, requirements for  
implementing function processing beyond the limitations  
5 on a specific program language are increasing. In each  
program language, a program is upgraded every time a  
new function is added. However, since such upgrading  
requires much time, it is hard to add new functions in  
quick response to advances of the technologies.

10 When the present invention is applied to the  
program recording scheme, a program control method  
which can implement function processing beyond  
limitations of conventional program languages such as  
"C", "Visual C", "JAVA", and the like on such languages  
15 can be provided.

When the present invention is applied to the  
program recording scheme, a program language which has  
command expandability even on the conventional program  
languages such as "C", "Visual C", "JAVA", and the like  
20 can be provided. As a consequence, an individual  
information processing apparatus (computer) can append  
function processing beyond the limitations on the  
conventional program languages.

Important points of the present invention will be  
25 summarized below.

Information created according to a recording  
format (recording scheme) complying with standards for

recording video information, audio information, still picture information, and the like on an information recording medium is recorded on the information recording medium as "common information 2001 (FIG. 12)".

5 This common information 2001 includes program (software) information created according to conventional program language rules (command rules) such as "C", "Visual C", "JAVA", or the like.

10 Furthermore, information created in a recording format (recording scheme) which is used for implementing a function unique to the manufacturer of an information recording/playback apparatus or information recording medium and does not comply with standards is recorded at a location different from the  
15 recording location of common information 2001 on the information recording medium as "specific information 2002 that can be used by only a specific manufacturer" shown in FIG. 12. This specific information 2002 that can be used by only a specific manufacturer includes  
20 expanded program (software) information created using new command information, which does not comply with conventional program language rules (command rules) such as "C", "Visual C", "JAVA", or the like.

Also, to allow use of specific information 2002,  
25 "link information 2003" that indicates the relationship between common information 2001 complying with standards and specific information 2002 that can be

used by only a specific manufacturer is recorded on the information recording medium.

Link information 2003 describes:

•manufacturer information or model information of  
5 information recording/playback apparatuses that can be used for each specific information 2002; and

•"information that pertains to the link pattern of specific information" indicating the relationship between each specific information 2002 and common  
10 information 2001.

In the description of the embodiment, an information recording/playback apparatus and recording scheme for recording video information, audio information, still picture information, and the like  
15 on an information recording medium, and playing back information from the information recording medium have been described. However, the present invention is not limited to such specific apparatus and scheme, and the above embodiment can be similarly applied to a program  
20 language having command expandability even on conventional program languages such as "C", "Visual C", "JAVA", or the like.

In this case,

•an information processing apparatus (computer)  
25 corresponds to the information recording/playback apparatus;

•a program (software) created according to

conventional program language rules such as "C",  
"Visual C", "JAVA", or the like corresponds to common  
information 2001 complying with standards;

5       •an HDD (hard disc drive) or an optical disc such  
as an MO, DVD-RAM, or the like, which records the  
program (software), corresponds to the information  
recording medium;

10       •program (software) data created according to  
original command information, which is created by the  
information processing apparatus (computer) and does  
not comply with conventional program language rules  
such as "C", "Visual C", "JAVA", or the like  
corresponds to specific information 2002 that can be  
used by only a specific manufacturer; and

15       •a call command link command (anchor information)  
called between the two programs (software) corresponds  
to link information 2003.

20       Furthermore, in this case, in the information  
content list of one link information shown in FIG. 13A,  
the information contents of drive manufacturer ID  
information (drive manufacturer name or the like) 2035  
that can use specific information associated with this  
link information are changed to "manufacturer ID  
information 2035 of an information processing apparatus  
25 (computer) that can use specific information associated  
with this link information"; and

•model information 2073 that can use specific

information is changed to "model information 2073 of an information processing apparatus (computer) that can use specific information.

5 The outline of information recording by the information recording apparatus (information recording/playback apparatus shown in FIG. 10) according to the present invention will be summarized below with the aid of FIG. 30.

10 As shown in FIG. 30, the information recording scheme of the present invention has a plurality of processes. The first process (ST1) records common information (2001) which can be commonly played back by a plurality of types of information playback apparatuses provided by different manufacturers or  
15 distributors, and complies with common standards. The second process (ST2) records specific information (2002) which can be played back by only an information playback apparatus of a specific type, which is provided by a specific manufacturer or distributor.  
20 The third process (ST3) records link information (2003) indicating links between the common information and specific information.

The link information (2003) recorded in the third process contains number information (2044) indicating  
25 the number of link designation locations in the common information. Also, the link information (2003) recorded in the third process contains at least one

ID information (character code) of ID information  
(character code corresponding to ID information)  
indicating the manufacturer of the information playback  
apparatus of the specific type, and ID information  
5 (character code corresponding to ID information)  
indicating the distributor of the information playback  
apparatus of the specific type. Furthermore, the link  
information (2003) recorded in the third process  
includes update history information.

10           The fourth process (ST4, ST5) records information  
indicating that link information has been updated  
in the update history information when the link  
information has been updated.

Each information mentioned above is recorded on  
15 the information recording medium by information  
recording/reproducing unit 101 serving as recording  
means. As a result, the common information, specific  
information, and link information are recorded on the  
information recording medium, as shown in FIG. 12.

20           The outline of information playback by the  
information recording apparatus (information  
recording/playback apparatus shown in FIG. 10)  
according to the present invention will be summarized  
below with the aid of FIG. 31.

25           Note that the information recording medium to be  
played back comprises first, second, and third areas,  
as shown in FIG. 12. The first area records common

information (2001) which can be commonly played back by a plurality of types of information playback apparatuses provided by different manufacturers or distributors, and complies with common standards.

5 The second area records specific information (2002) which can be played back by only an information playback apparatus of a specific type, which is provided by a specific manufacturer or distributor. The third area records link information (2003), which  
10 indicates links between the common information and specific information, and contains at least one of ID information indicating the manufacturer of the information playback apparatus of the specific type, and ID information indicating the distributor of the  
15 information playback apparatus of the specific type.

The information playback apparatus of the specific type (information recording/playback apparatus shown in FIG. 10), which plays back the information recording medium to be played back comprises memory 1534 serving  
20 as ID information storage means (character code memory means). Memory 1534 stores at least one ID information (character code) of ID information (character code corresponding to ID information) indicating the manufacturer of the information playback apparatus of  
25 the specific type, and ID information (character code corresponding to ID information) indicating the distributor of the information playback apparatus of

the specific type.

As shown in FIG. 31, an information playback method of the present invention comprises a plurality of processes.

5           The first process (ST11) plays back a disc  
(plays back common information and link information).  
The second process (ST12) compares ID information  
(character code corresponding to ID information) stored  
in memory 1534 with ID information (character code  
10           corresponding to ID information) contained in the link  
information played back from the information recording  
medium. If it is confirmed in the third process (ST13)  
that these two pieces of ID information match each  
other, specific information is played back in the  
15           fourth process (ST14). Or if it is confirmed in the  
third process (ST13) that these two character codes  
match each other, ID information stored in memory 1534  
is compared with that contained in the link information  
played back from the information recording medium. If  
20           it is confirmed that these two pieces of ID information  
match each other, specific information is played back  
in the fourth process (ST14).

Each information mentioned above is played back  
from the information recording medium by information  
25           recording/reproducing unit 101 serving as playback  
means.

The correspondence between the data structure

built on the information recording medium and data shown in FIGS. 1A to 1F and FIGS. 13A to 13C will be explained below with reference to FIGS. 32 to 35.

As shown in FIG. 32, a DVD\_RTR directory is contained in a root directory. The DVD\_RTR directory contains RTR.IFO, RTR\_MOV.VRO, RTR\_STO.VRO, and RTR\_STA.VRO. Furthermore, the RTR.IFO contains an RTR video manager (RTR\_VMG). This RTR video manager (RTR\_VMG) corresponds to control information 1011 shown in FIG. 1D. The RTR\_MOV.VRO corresponds to video objects 1012 shown in FIG. 1D, the RTR\_STO.VRO to picture objects 1013 shown in FIG. 1D, and RTR\_STA.VRO to audio objects 1014 shown in FIG. 1D.

As shown in FIG. 33, the RTR video manager (RTR\_VMG) contains RTR video manager information (RTR\_VMGI), movie AV file information table (M\_AVFIT), still picture AV file information table (S\_AVFIT), original PGC information (ORG\_PGCI), user defined PGC information table (UD\_PGCIT), test data manager (TXTDT\_MG), and manufacturer's information table (MNFIT). Also, the RTR video manager information (RTR\_VMGI) corresponds to video title set information 1106 shown in FIG. 1F. The movie AV file information table (M\_AVFIT) and still picture AV file information table (S\_AVFIT) correspond to video object information 1107 shown in FIG. 1F. The original PGC information (ORG\_PGCI) and user defined PGC information table

(UD\_PGCIT) correspond to PGC control information 1103 and cell playback information 1108 shown in FIG. 1F. The manufacturer's information table (MNFIT) corresponds to link information 2003 shown in FIG. 12. This link information 2003 shown in FIG. 12 is contained in edit control information 1023 shown in FIG. 1E.

As shown in FIG. 34, the manufacturer's information table (MNFIT) contains the number of pieces of manufacturer's information, manufacturer's information #1 (MNFI#1), ..., manufacturer's information #n (MNFI#n). The number of pieces of manufacturer's information corresponds to number 2044 of link designation locations in common information complying with standards shown in FIG. 13B.

Manufacturer's information #1 (MNFI#1) has a configuration shown in FIG. 35. MNF\_ID corresponds to drive manufacturer ID information 2035 shown in FIG. 13A. REC\_TM corresponds to last recording/change time (date) information 2061 of link information shown in FIG. 13C.

According to the embodiment of the present invention described above, the following effects can be obtained.

(1) The present invention for the first time assures the recording location of information (original information other than common information 2001

complying with standards) originally created by the  
manufacturer of an information recording/playback  
apparatus which can record/play back information  
on/from an information recording medium (recording area  
of specific information 2002) on the information  
recording medium. As a result, the manufacturer of the  
information recording/playback apparatus can record  
original information on the information recording  
medium without any restraints of the standards.

(1-1) The present invention for the first time  
assures the recording location (recording area of  
specific information 2002) of program (software) data  
created according to original command information,  
which does not comply with conventional program  
language rules such as "C", Visual C", "JAVA", or the  
like by an information processing apparatus (computer)  
on an information recording medium that records program  
(software) data. As a result, in order to provide  
an original function by the information processing  
apparatus (computer), program (software) information  
according to command information, which does not comply  
with conventional program language rules such as "C",  
Visual C", "JAVA", or the like and is originally  
created by the information processing apparatus  
(computer) can be appended.

(2) Since original information other than common  
information 2001 complying with standards can be

recorded in the area of specific information 2002  
that can be used by only a specific manufacturer,  
information corresponding to an original function set  
by the manufacturer of the information recording/  
5 playback apparatus can be recorded in the recording  
area of specific information 2002 without being limited  
by the functions set according to the conventional  
standards. Consequently, each manufacturer can provide  
its original function to the information recording/  
10 playback apparatus, and this leads to originality and  
differentiation among individual information recording/  
playback apparatuses. In this manner, development of  
information recording/playback apparatuses in terms of  
functions based on the principle of competition is  
15 expected.

(2-1) Since program (software) information  
according to command information which does not comply  
with conventional program language rules such as "C",  
"Visual C", "JAVA", or the like and is originally  
20 created by an information processing apparatus  
(computer) can be recorded in the area of specific  
information 2002 that can be used by only a specific  
manufacturer, each manufacturer can provide its  
original function to the information processing  
25 apparatus (computer), and this leads to originality and  
differentiation among individual information processing  
apparatuses (computers). Hence, development of

information processing apparatuses (computers) in terms of functions based on the principle of competition is expected.

5 (3) Since original information other than common information 2001 complying with standards can be recorded in the area of specific information 2002 that can be used by only a specific manufacturer, information corresponding to an original function set by the manufacturer of the information recording/  
10 playback apparatus can be recorded in the recording area of specific information 2002 without being limited by the functions set according to the conventional standards. As a consequence, a new function can be added to an information recording/playback apparatus  
15 in quick response to advances of the technologies as needed, and the functions of the information recording/playback apparatus can be advanced in correspondence with such technological advances.

(3-1) Since program (software) information  
20 according to command information which does not comply with conventional program language rules such as "C", "Visual C", "JAVA", or the like and is originally created by an information processing apparatus (computer) can be recorded in the area of specific  
25 information 2002 that can be used by only a specific manufacturer, each manufacturer can provide its original function to the information processing

apparatus (computer). Hence, a new function can be added to an information processing apparatus (computer) in quick response to advances of the technologies as needed, and the functions of the information processing apparatus (computer) can be advanced in correspondence with such technological advances.

(4) Since link information 2003 is provided, the relationship between common information 2001 complying with standards and specific information upon use can be clarified. As a consequence, an information playback apparatus can use specific information 2002 without any errors.

(4-1) Since link information 2003 is provided, the relationship between common information 2001 complying with standards and specific information upon use can be clarified. As a consequence, an information processing apparatus (computer) can use specific information 2002 without any errors.

(5) Since link information 2003 is provided and contains manufacturer information or model information of an information recording/playback apparatus that can be used for each specific information 2002, the information recording/playback apparatus can automatically determine usable specific information 2002 very easily. As a result, in information recording/playback apparatuses manufactured by all the manufacturers, specific information 2002 can be utilized without any

errors while assuring high reliability.

The present invention can provide the following  
information recording medium, information recording  
method and apparatus, and information playback method  
and apparatus:

(1) an information recording medium which allows  
to achieve differentiation and originality of functions  
in units of models of information playback apparatuses  
provided by different manufacturers or distributors;

(2) an information recording method which records  
information on an information recording medium to be  
able to achieve differentiation and originality of  
functions in units of models of information playback  
apparatuses provided by different manufacturers or  
distributors;

(3) an information recording apparatus which  
records information on an information recording medium  
to be able to achieve differentiation and originality  
of functions in units of models of information playback  
apparatuses provided by different manufacturers or  
distributors;

(4) an information playback method which plays  
back information from an information recording medium  
on which information is recorded to be able to achieve  
differentiation and originality of functions in units  
of models of information playback apparatuses provided  
by different manufacturers or distributors;

(5) an information playback apparatus which plays back information from an information recording medium on which information is recorded to be able to achieve differentiation and originality of functions in units of models of information playback apparatuses provided by different manufacturers or distributors;

(6) an information recording medium which has a data structure with high expandability of functions;

(7) an information recording method which records a data structure with high expandability of functions on an information recording medium;

(8) an information recording apparatus which records a data structure with high expandability of functions on an information recording medium;

(9) an information playback method which plays back information from an information recording medium on which a data structure with high expandability of functions on an information recording medium is recorded; and

(10) an information playback apparatus which plays back information from an information recording medium on which a data structure with high expandability of functions on an information recording medium is recorded.

Additional advantages and modifications will readily occur to those skilled in the art. Therefore, the invention in its broader aspects is not limited to

the specific details and representative embodiments shown and described herein. Accordingly, various modifications may be made without departing from the spirit or scope of the general inventive concept as defined by the appended claims and their equivalents.
